# Increases Your Production

## “PMS”

### THE “RED RIBBON” BELT

Increases production by giving greater efficiency in transmitting the power that is so costly to develop, by minimizing “break-downs” and stops for readjustments.

These are not mere idle claims, but actual achievements by “P M S” in many of Canada’s leading plants. Greater adhesion to the pulley, great strength, even pliability, and remarkable resistance to the effects of heat, cold and moisture are the reasons for its success.

- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Ground Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.
- Summary Report. The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memorandum 111. The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

- Communications should be addressed to The Director, Geological Survey, Ottawa.

Handbook for  
**FIELD GEOLOGISTS**

By C. W. HAYES, Ph. D.,

Late Chief Geologist, U. S. Geological Survey.

**THIRD EDITION, REVISED AND REARRANGED**

By **SIDNEY PAGE,**

Geologist in Charge, Division of Geology,  
U. S. Geological Survey.

Gives in a practical, convenient way, real, serviceable data useful to all geologists.

166 pages. 4½ by 6¾. 20 figures and 2 plates.  
Flexible binding, \$2.50.

Elements of  
**ENGINEERING GEOLOGY**

By **H. RIES, Ph. D.,**

and **THOMAS L. WATSON, Ph.D.**

Emphasizes the practical application of the subjects treated to engineering work.

356 pages. 5½ by 8½. 252 figures. Cloth, \$3.75.

PROVINCE OF ONTARIO

# Minerals

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.         | Value.      | Year.         | Value.       |
|---------------|-------------|---------------|--------------|
| 1891 .. . . . | \$4,705,672 | 1906 .. . . . | \$22,388,383 |
| 1896 .. . . . | 5,235,003   | 1911 .. . . . | 41,976,797   |
| 1901 .. . . . | 11,831,086  | 1916 .. . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

**THOS. W. GIBSON,**  
Deputy Minister of Mines,  
TORONTO, CANADA.

GARDEN CITY PRESS, GARDENVALE, QUE.

The Home of  
The  
Canadian Mining Journal  
GARDENVALE, QUE.

Garden City Press is situated on the Toronto to Montreal and Ottawa to Montreal lines of the C.P.Rly. and G.T.Rly., adjoining Macdonald Agricultural College. The railway station, telegraph and express office on either line is Ste. Annes, but the post office, which is located in our own plant, is Gardenvale, Que.

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, \$76,177,403; Lode Gold, \$105,557,977; Silver, \$55,259,485; Lead, \$48,330,575; Copper, \$166,393,488; Zinc, \$21,848,531; Coal and Coke, \$225,409,505; Building Stone, Brick Cement, etc., \$34,072,016; Miscellaneous Minerals, \$1,210,639; Making its mineral production to the end of 1920 show an

**Aggregate Value of \$734,259,619**

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for the year 1916, \$42,290,462; for the year 1917, \$37,010,392; for the year 1918, \$41,782,474; for the year 1919, \$33,290,313; 1920, \$35,543,084; 1921, \$28,066,641.

**Production During last ten years, \$336,562,897**

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected: 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia.  
THE HON. THE MINISTER OF MINES,

MADE IN CANADA

A—rigid pillar shaft; B—sleeve eccentric; C—flanged head liner on which head is adjusted; D—non-rotating crushing head; E—cast steel gear; F—jack screws for adjusting head; G—split distance rings (set furnished for different bottom openings); J—expansible taper bushings; K—gear driven oil pump.

The rigid, non-rotating, high carbon steel pillar shaft is practically indestructible and braces up the whole machine to a remarkable degree.

The rigid shaft and sleeve eccentric shorten up the crusher over 30 per cent. The low structure and heavily ribbed walls indicate why Tel-smith is the lightest in total weight, but heaviest per inch of height of any gyratory ever built.

The eccentric extends from the bottom spider through the head, almost to the crown. The bearings are machined babbit sleeves furnished complete, ready for service and are approximately four times larger than in crushers of the lever shaft type. Lubricated by oil under pressure, with absolute exclusion of dirt, these bearings are economical both in consumption of babbit and power.

The Parallel Crushing Stroke is perhaps the most valuable feature of the machine. The eccentric acts directly on the head, producing a horizontal movement, uniform at all points of the bowl. The full stroke is extended on the mass just as it enters the bowl, speeding up the whole process.

The crushing stroke is a horizontal gyratory movement which cracks the rock without grinding action on the head or concave surfaces. The head cannot turn on head liner yet is readily adjusted by jack screws.

Write for bulletins explaining these and other Tel-smith features in detail.

# Inside Facts About the “Tel-smith” Primary Breaker

As the eccentric and head liner extend through the head, it is necessary to employ a very large crushing cone and bowl providing large crushing surfaces, receiving openings and great capacity.

Discharge is by gravity from the bottom. The discharge chute is independent of the crusher and can be set for right hand, left hand, forward or rear discharge.

Wearing parts are manganese steel or chilled iron, or a chilled iron head combined with manganese concaves — or vice versa. Smooth or corrugated heads are furnished on sizes up to and including the No. 6. On the larger sizes, corrugated heads only are used.

The driving gears are cast steel, running in oil, with dirt excluded by oil pressure, so that wear occurs very slowly. The pump drive gears are also cast steel, completely enclosed and lubricated by oil from the countershaft box.

The size of the feed openings and the parallel stroke makes it possible to crush bigger cubes than in any other breaker of the same opening.

## TRANSMISSION MACHINERY

We can give you the largest range of patterns in Canada to choose from for gears, pulleys, bearings and bridgetrees. Gear teeth either cut or cast. Special transmission machinery built to specifications.

### CASTINGS

Clean, sound, reliable castings in malleable iron, cast iron, steel, aluminum brass and bronze. Prompt deliveries.

## THE NEW YEAR

The past year has been fruitful of beneficent results to the mining industry of Canada. The most remarkable of these are intangible, though plainly evident.

Throughout the year there have been unmistakable manifestations of a new and stronger consciousness, let us call it "class consciousness" for lack of a better phrase, in the men behind the industry. There is little, however, of the self-seeking that is always implied in that objectionable phrase. Honest, earnest, and disinterested citizens have striven diligently for the welfare of the profession of mining engineering, and for the advancement of the industry. That their striving has borne fruit is apparent in more than one direction.

The interest displayed by the Dominion Government, through the Deputy Minister of Mines, Dr. Charles Camsell, in investigating the overseas markets for Canadian mineral products, is a pleasing sign of vitality. We hope that it will lead either to an extension of the usefulness of the Mines Branch, or to a permanent organization the sole purpose of which would be to stimulate our export trade.

Of the conjoint efforts of the Dominion and Ontario Governments to promote the utilization of peat we can speak only with the warmest commendation. It is to the credit of both Governments that the work was undertaken. That they were incited thereto by sound prevision, and not by popular demand, is all the more creditable. Peat, that "moss-born jewel", as the ardent poet puts it, is assuredly to become the future domestic fuel of the greater part of Quebec and Ontario. The case may be taken as proven.

Concerning the Dominion Government's lignite briquetting plant in Saskatchewan we have heard little. Progress made in other countries since the inception of this enterprise amply attests its utility. The public positively requires education as regards the new science of fuel economy. Only by this means will the Government's technical departments win the support that they deserve.

The renewed attempt of the Ontario Government, inspired by the Hon. Mr. Mills, Provincial Minister of Mines, to discover a tonic for the iron industry of the Province is praiseworthy. Its efficacy remains to be demonstrated.

Each of these movements is significant; together they presage the rapidly approaching day when governments will put their shoulders to the wheel of pro-

gress and furnish constructive and continuous assistance to the discovery and appraisal of mineral deposits in every part of Canada.

The Canadian Institute of Mining and Metallurgy is approximating, year by year, more closely to the representative society that was the ideal of its founders. The Institute has weathered many a gale. Whatever troublous times may be ahead, there need be no fear as to its survival, so long, that is, as it lives within its income. Perhaps a New Year's resolution is in order.

As indicated by several articles appearing in this issue, mining and metallurgical progress in Canada has been sound and satisfactory during the past twelve months. No country can ever be self-contained or self-sufficing in relation to scientific and technical growth. In these matters the comity of nations engenders an admirable spirit of mutual helpfulness that is the antithesis of commercialism. It is pleasant to know that Canada is now on an equal footing with her sister nations in the World Exchange of scientific thought and technical achievement.

It is noticeable that the larger Canadian mining corporations are devoting much more effort and money to the search for payable ore deposits than ever before. Moreover, the fact that Canada offers a plethora of inducements to the investor is impressing itself more and more effectively upon the responsive minds of British and United States investors. There is more than mere rhetoric in this statement. It is within the bounds of accurate statement to assert that never in Canada's history has so much outside money been available for the development of her mining industry.

A new spirit is immanent in Canadian mining. Mining is not any more a thing to be apologized for. It has become a respectable industry, conducted on business principles. The mining man resents the activities of the charlatan more deeply and more promptly than anyone else resents them. Mining has been made a clean business in Canada, and a clean business it will remain. And much was done to foster this cleanliness during the year 1922. *The Canadian Mining Journal* will continue to make war upon all enterprises that savour of unfairness to the investing public.

\* \* \*

As the Old Year passes and the New Year dawns, *The Canadian Mining Journal* extends to its readers the heartiest good wishes. May peace and prosperity be the portion of each and all during the Year of Our Lord, Nineteen Hundred and Twenty Three.

## OUR REVIEWS

A review is essentially retrospective. A study of the past is, however, mainly profitable as it bears on action in the present and future. It is this point of view that has induced us to devote the present number of *The Canadian Mining Journal* to the results attained in our wide-spread mineral districts during the past twelve months.

The record is, in general, a pleasant one to contemplate, in spite of the disturbing influences of a world still turbulent and distracted and of a native citizenry not yet firmly settled in peaceful pursuits.

Mr. S. J. Cook, whose prompt reports at intervals throughout the year have kept the public in touch with the march of events in the mining industry, demonstrates a satisfactory growth in the Dominion's total for the year. His separate report on coal emphasizes the fact that this much-discussed product of the mines is the most important single item in our material civilization.

Mr. Thomas W. Gibson, a veteran of the mining industry in Ontario and one of its leading spirits, gives his usual vivid account of what the premier mineral province has contributed during the year. Particularly satisfactory is his reference to the proved continuity of the northern gold deposits and the hope for their extension still further, both vertically and longitudinally. He renews the emphasis laid by the provincial geologists upon the proved geological associations of the gold, which constitutes a word to the wise. The whole review has a distinctly forward look.

The record for British Columbia shows steady progress, which promises to be even more substantial during 1923. While a few outstanding properties have furnished the bulk of the output, there is a multitude of the lesser producers that have proved through years to be such an important factor in the province's mineral industry.

Quebec's mineral production still depends mainly, as heretofore, upon asbestos. But Mr. Theo. C. Denis, the chief public protagonist of the province's mineral industry, is able to record this year the commencement of what promises to be a gold mining industry of first-rate dimensions. If this development continues to the point of substantial production, the new year will see a general interest in Quebec's mineral resources that has never yet been accorded them.

Nova Scotia mineral production, still dependent almost exclusively upon coal, is gauged in a critical way by Mr. F. W. Gray, one of Canada's foremost authorities on coal. His hopeful view is certainly not tinged with undue optimism, and augurs well for the future. Mr. Beveridge's hopes for the province's gold industry are not without substantial foundation, and their realization is long overdue.

The infant mining industry in Manitoba has been almost strangled by the weight of illicit script hung about it; but it promises to survive this untoward and

illogical treatment, and to fulfil its first promise, according to Dr. J. S. DeLury, who knows well the several fields.

In addition to these records from the geographical divisions of the Dominion, we have four general reviews. Mr. Alexander Gray presents a study of the trend of investment in mines during the year. Comparatively few realize the position of prime importance held by sound, well-directed investment in the mining industry. Organized and logical investment in mines has been the last of the phases of the industry to receive consistent attention. It is still far from being in a satisfactory state, and deserves the closest attention of those directing the industry's destinies.

The current technique of Canadian mining and metallurgy is reviewed by Professors Graham and MacKay, both of them practical technologists whose experience in mine and mill gives them not only a comprehension of the technical man's problems and difficulties, but a full appreciation of the results attained.

Mr. Malcolm's duties throughout the year keep him in intimate touch with what our geologists have accomplished. Therefore his discriminating comment on results for 1922 is worth close attention.

We have asked Mr. N. B. Davis to review the position of Canada's Ceramic industry for this issue, not because of its present relative importance, but because it presents opportunities for development and expansion of which few are aware. The ceramic industries deserve much more attention than they are receiving at present. They are "prosaic", to be sure, but highly important.

## THE NEW YEAR

This is the time of moral restitutions  
Which take the form of penal resolutions.

\* \* \*

For every sin wherewith my scroll is blackened,  
For every day my stern control has slackened,  
For every time—I tell the country all—  
That I have visited old Montreal,  
I'll make a vow, to be observed and kept:  
Not like last year's, to fade away unwept.  
I vow I'll lead a blameless life and quiet,  
Forgoing all that makes for noise and riot;  
Subscriptions that I've owed the Journal, lo,  
These many years, I'll pay, don't say me no!  
I'll go to church on Sundays with the best,  
And through the year I'll stand the acid test.  
Though all the hosts of Satan tempt me sore,  
Unhesitant I'll show them to the door.

\* \* \*

On looking up my diary I see  
That last year's resolutions—woe is me!—  
Were word for word the duplicates of these:  
But I'm in earnest now—believe me—please!

J. C. M.

# Mineral Production of Canada in 1922

By S. J. COOK \*

The value of the mineral production of Canada in 1922 has been estimated at \$18,622,000 as compared with \$174,315,653 in 1921. The past year's output was made up as follows: metallics, \$61,731,000; non-metallics \$83,891,000; structural materials and clay products \$35,000,000.

The output of gold, silver and lead was greatly increased, and the recovery in the production of copper and nickel during the latter part of the year was most encouraging and fair gains were made. The slight decrease in coal was accounted for by labor conditions.

Comparative statistics of the value of the mineral production for the past ten years are given below:

Annual Values of Metallic and Non-Metallic Production

| Year           | Metallic    | Non-Metallic                  |                                              | Total       |
|----------------|-------------|-------------------------------|----------------------------------------------|-------------|
|                |             | Fuels and other non-metallics | Structural or clay and stone quarry products |             |
| 1913 . . . . . | 66,361,351  | 48,463,709                    | 30,809,752                                   | 145,634,812 |
| 1914 . . . . . | 59,386,619  | 43,373,571                    | 26,009,227                                   | 128,863,075 |
| 1915 . . . . . | 75,814,841  | 43,373,571                    | 17,920,759                                   | 137,109,171 |
| 1916 . . . . . | 106,319,365 | 53,414,983                    | 17,467,186                                   | 177,201,534 |
| 1917 . . . . . | 106,455,147 | 63,354,363                    | 19,837,311                                   | 189,646,821 |
| 1918 . . . . . | 114,549,152 | 77,621,946                    | 19,130,799                                   | 211,301,897 |
| 1919 . . . . . | 73,262,793  | 76,002,087                    | 27,421,510                                   | 176,686,390 |
| 1920 . . . . . | 77,939,630  | 108,027,947                   | 41,892,088                                   | 227,859,665 |
| 1921 . . . . . | 49,343,232  | 87,833,161                    | 35,139,260                                   | 174,315,655 |
| 1922 . . . . . | 61,731,000  | 83,891,000                    | 35,000,000                                   | 180,622,000 |

The outstanding feature of the metal production was the excellent gain made in the output of gold by the two important producing provinces, Ontario and British Columbia. The total gold production for Canada during the year amounted to more than 1,200,000 ounces and compared with the 1921 production showed an increase of 31.0 per cent. The increased prices and the lively markets for silver and lead were reflected in excellent gains in production. Zinc production remained about the same. Cobalt increased slightly most of the gain being made in the latter part of the year, while copper and nickel as might have been expected, declined appreciably.

Although the production of copper for the first six months showed a decrease from the output of the corresponding period in the preceding year, the loss was more than overcome during the later months and copper shows a creditable increase in the annual estimate now reported. This gain was wholly due to the resumption of nickel-copper smelting activities.

Although the smelter production of blister and converted copper in British Columbia was less than in 1921 the recovery and rise in the price of copper did not occur until about the middle of the year and some important copper mines which were active in 1921 did not appear on the shipping list in 1921 until nearly the close of the year. The last half of the year shows a decided improvement in the copper industry and 1923 will likely show a considerable resumption of activity in this field.

The inactivity of the smelting departments of the

\* Chief of the Mining, Metallurgical and Chemical Branch, Dominion Bureau of Statistics.

International Nickel Company in the earlier part of the year and of the British America Nickel Corporation throughout the entire year accounted for the small production of nickel. The accumulated stocks of nickel have now been fairly well absorbed and the immediate future is much brighter than any time during the past two years.

Among the non-metallics the output of coal, considering the great loss of time through strikes, was most encouraging. Asbestos shipments during the latter part of the year were considerably increased and while the producing mines operated on a much reduced scale as compared with two years ago, conditions were such towards the end of the year that the

HON. CHARLES STEWART  
Federal Minister of Mines

miners were assured of work in the coming months and the fear of the repetition of the unemployment that prevailed last winter was reduced to a minimum.

The ten principal products of the mineral industry in Canada in 1922 in order of the values assigned were: coal \$68,349,500; gold \$25,110,500; silver \$16,633,500; nickel \$8,684,000; copper \$6,832,800; lead \$6,141,553; asbestos \$5,200,000; natural gas \$4,688,400; zinc \$3,091,500; and salt \$1,850,000.

### Coal

The output of coal from Canadian Mines during the twelve months of the calendar year 1922 was approximately 14,210,000 tons at an estimated value of \$68,349,200 as compared with 13,057,493 tons, valued at \$72,451,066 in 1921, 16,046,764 tons valued at \$82,496,538 in 1920, and 13,919,096 tons valued at \$55,622,670 in 1919. The coal statistics for the year are covered by a separate statement on another page.

### Gold

The remarkable prosperity of the gold mining industry during the year just closed was the most outstanding feature of the year's production. The 1,200,000 ounces production speaks for itself. Although the mineral resources of Ontario have been pretty thoroughly known for more than twenty years the development of the gold reserves first noted in 1909 did not extend to profitable commercial production until about 1912. The war restricted expansion and although in the post-war period the favorable exchange situation contributed to the advance of the industry, it was not until 1922 that the full stride of production was obtained and the million-ounce annual output definitely accomplished. A continued steady increase in production may be expected. The gains in 1922 were due to the steady development of the Northern Ontario gold mines, with Hollinger holding not only first place in Ontario but first place among the gold producing mines of the world. McIntyre-Porcupine and Dome were close contestants throughout the year for second place. A great amount of development work was carried on and the list of producing mines was lengthened.

In British Columbia the increase was also marked and although one of last year's producers, the Nugget Mine was closed throughout the year the provincial output was increased by the re-opening of the Nickel Plate mine owned by the Hedley Gold Mining Co., which had been idle throughout 1921, and by the phenomenal production from the Premier Mine near Stewart. Throughout the year the Premier Mining Company shipped each month about 3,000 tons of high-grade ore running in the neighborhood of \$80 a ton and 3,000 tons of medium grade averaging \$35 per ton. It milled between 3,000 and 4,000 tons of lower grade ore in its own concentrating and cyanide plant and it has been estimated that the mine has been turning out ore to the value of \$400,000 each month, the high-grade and concentrate going to the Tacoma, Wash., smelter and the medium and lower grade ores going to the Granby smelter at Anyox, B.C.

Reports from all the gold fields indicated wonderful activity in every camp.

### Silver

The production of silver continued favorably in spite of the prevailing medium price for the metal, and amounted in all to 15,726,000 ounces valued at \$10,633,500 for the year. As compared with the figures for a year ago there was an increase of more than two million ounces. The producing areas in order of importance were Ontario, British Columbia and the Yukon. Quebec and Manitoba did not produce silver in any great amount during the period, and Nova Scotia contributed only the few ounces contained in gold bullion shipped to the Royal Mint. In the Cobalt

area both the Nipissing and the Mining Corporation increased their production of silver bullion, as did also the O'Brien and Coniagas Mines. In British Columbia the greatest increase was made in the Skeena district and was accounted for by new shippers, the most important of which was the Premier. The recovery in the Slovan district, where mining in 1921 was retarded because of the reduced market value of silver and its associated metals, was apparent, with a much brighter future in view. A considerable portion of this activity should probably be credited to the new schedule of rates offered by the Consolidated Mining and Smelting Company, to operators producing silver-lead-zinc ores.

### Lead

More lead was produced in Canada during the first half of the year just closed than in the entire twelve months of the preceding year. The output in 1922 from all sources amounted to 98,738,000 pounds having an estimated value of \$6,141,000 as against the previous year's production of 66,679,000 pounds valued at \$3,828,000.

The most outstanding development was the increased production of lead by the Trail smelter. Receipts at the Trail smelter during the last few months of the year were in excess of the records for any previous period in the company's history. The output from the Galletta smelter in Ontario was maintained at about the same level as in the preceding year, and a small quantity of lead was also produced at Notre-Dame des Anges in Quebec.

The price of lead showed a gradual recovery during 1922 from the low average on the St. Louis market of 4.363 cents per pound in 1921 and reached a high of 6.868 cents a pound on the same market in November. The Montreal price of lead averaged 5.742 cents a pound in 1921 and 6.22 cents in the year just closed.

### Natural Gas

The output of natural gas from Canadian fields in 1922 amounted to about 15,000,000 thousand cubic feet valued at \$4,689,000. The quantity of gas produced was practically unchanged from the output in the preceding year, but the value in 1922 was approximately \$300,000 less.

Ontario retained the premier position and produced 8,600,000 thousand cubic feet while Alberta followed with an output of 5,500,000 thousand cubic feet. More than 900,000 thousand cubic feet was produced from the fields of New Brunswick.

### Copper

The production of copper in Canada since the close of the war has been only slight. The output during the first half of 1922 declined considerably below the production during the corresponding period of the previous year, but the resumption of operations by the nickel-copper smelters resulted in the annual production for 1922 rising about 3,500,000 pounds over the record for the preceding year. During the last six months of 1922, the nickel-copper smelters in Ontario produced more than 18,000,000 pounds of copper contained in matte. The production in British Columbia in the earlier part of the year was considerably handicapped by the high cost of fuel at the Trail smelter. The Granby Company at Anyox operated steadily throughout the year.

The rise in the price of copper that set in towards

the latter part of April proved an incentive to production and electrolytic copper in New York, averaging 13.338 cents per pound for the twelve months of 1922, was nearly eight-tenths of a cent above the 1921 average price.

### Asbestos

Asbestos mining in Quebec, in common with the other asbestos producing countries of the world, suffered a decline in 1921 which continued throughout the first half of 1922. During the past few months, however, there has been a considerable revival in this industry, and prospects are much better now than they have been at any time within the past two years.

The reduction in the percentage of royalty taxes imposed by the Provincial Government on all asbestos produced and sold will undoubtedly prove quite a stimulus to the industry as a whole. The manufacture of finished asbestos product is being looked forward to as a coming important industry in the Province of Quebec.

Two plants are presently supplying the local demand for asbestos papers, shingles and brake linings, but it has recently been announced that other companies will shortly enter this field. It is reported that a representative of one of the largest asbestos companies in England has been in Canada studying conditions and that if the negotiations now under way are carried to a successful conclusion, the capitalization of the companies engaged in this field will be more than doubled.

The output of asbestos in 1922 reached a total of approximately 139,000 tons of all grades, valued at \$5,200,000 as compared with 92,761 tons valued at \$4,906,230 in 1921. The appreciable percentage increase in production has been due almost entirely to the activity about the mines during the past three months.

### Zinc

The smelter recovery of zinc in 1922 was approximately one million pounds greater than in the preceding year and amounted in all to 54,000,000 pounds valued at \$3,092,000. As in other years the production was derived entirely from British Columbia and was derived almost exclusively from the Trail smelter.

The production of zinc by small operators in the past has progressed under many difficulties. Where a Slocan mill, for instance, produced both lead concentrate and zinc concentrate, it could readily market the lead concentrate, but there was more difficulty in disposing of the zinc product. Zinc ores and concentrates were formerly exported at heavy cost in freight and duty to United States smelters. The operators were recompensed for the zinc contents but lost valuable amounts of silver, and were penalized for any lead present. On the other hand, lead ores and concentrates containing considerable zinc proved very refractory when treated in the lead smelters in Canada, and as a result mine operators suffered a penalty per unit of zinc in their ores. Under these conditions zinc mining was handicapped and could not flourish except under such conditions as obtained in the late war. By the introduction of improvements in the electrolytic process carried on by the Consolidated Mining and Smelting Company it has been found possible to offer a schedule of smelter rates under which the mine operator will be enabled to market zinc ores and concentrates and receive payment for a considerable portion of the precious metal contents in addition to the zinc. While

zinc contained in lead ores may continue to be a loss, the penalty will be lowered and it is expected that the lead-zinc industry will benefit materially.

### Non-Metallics

Feldspar mining in the Province of Quebec has been growing apace during the last two years. The industry, which is an old one in the province, was given a great impetus by the discovery of a large body of cream, white orthoclase feldspar in Derry Township in the fall of 1920. From this deposit nearly 10,000 tons of high grade potash feldspar was shipped during 1921 and production during the past year has been well maintained. Interest in the production of feldspar has been marked, particularly during recent months.

The output of gypsum also showed a considerable improvement over the records of the preceding year and amounted in all to 429,000 tons valued at \$1,800,000 as compared with an output in 1921 of 386,000 tons valued at \$1,785,538.

\* \* \*

The increase in the production of metals during the past year amounting to approximately \$12,000,000 in value marked a resumption of progress in the metal mining field and points the way to greater prosperity. The slight decline in the production of non-metallic including coal amounts only to about \$4,000,000 in value and since the greater part of this decrease was due to loss of production caused by labour troubles, the slight set-back may be regarded as negligible. In the successful marketing of structural materials and clay products the revival of the building industry has played a great part and during the past year the production of these materials has been considerably increased; but owing to the fact that prices have at the same time declined, the value of the output in 1922 was only maintained at about the same level as in 1921.

The advance in mineral production as a whole, then, to a total value of \$180,622,000 may be considered as most propitious. Comparison with preceding years shows that 1920, 1918 and 1917 were the only years in which this value was exceeded.

Taken all in all the mining industry in Canada may be regarded as in a sound financial and industrial condition, with a bright future immediately ahead of it.

### COAL IN CANADA, 1922

BY S. J. COOK\*

#### Output

The output of coal from Canadian mines during the twelve months of the calendar year 1922 was approximately 14,210,000 tons as compared with 15,057,493 tons in 1921; 16,946,764 tons in 1920; and 13,919,096 tons in 1919. The great strike that tied up the United States coal mines for several months was reflected in Canada and resulted in a loss of 1,199,427 working days. Eleven disputes between employees and employers occurred in the coal mining industry in Canada during the eleven months ending November, nine of which were in Alberta and South-eastern British Columbia, and the other two in Nova Scotia. In all 23,901 men were effected, and of the time lost, 931,960 days were lost in the strike which began on April 1st, and 260,034 days time was lost in the short strikes originating in August. Having

\* Chief of the Mining, Metallurgical and Chemical Branch, Dominion Bureau of Statistics.

in mind the fact that over one million working days that was lost by the employees of the coal mining industry during the year, the output of fourteen and one quarter million tons may be considered quite satisfactory. Alberta coal mine output amounted to 5,387,000 tons, a little more than half of which was lignite and made up the balance bituminous. Nova Scotia contributed 5,349,000 tons and occupied second place among the coal-producing provinces. British Columbia amounted for 2,936,000 tons, and New Brunswick and Saskatchewan followed with 287,000 tons and 250,000 tons respectively.

#### Interprovincial Shipments of Canadian Coal

Four million tons of Canadian coal moved in interprovincial trade during the year and of this amount about 2,443,000 tons was bituminous coal, the balance being mostly lignite. Shipments of Nova Scotia coal to other Canadian provinces, principally New Brunswick, Prince Edward Island and Quebec, amounted to almost 2,000,000 tons. The province of Quebec received about 1,600,000 tons of Canadian coal during the year, an increase of nearly 700,000 tons above the receipts of Canadian coal in the preceding year and fully six times as much as reached this province in 1920.

COAL MADE AVAILABLE FOR CONSUMPTION IN 1922 BY PROVINCES SHOWING THE OUTPUT, EXPORTS INTERPROVINCIAL SHIPMENTS AND IMPORTS FROM THE UNITED STATES AND GREAT BRITAIN

| Province                            | Output     | Canadian Received from other Provinces | Coal Shipped to other Provinces | Exported  | Imported From United States | Great Britain | Coal Available for Consumption |

The restoration of the St. Lawrence trade to the normal pre-war figure of 2,000,000 tons per season was therefore almost overtaken during the twelve months just closed. Shipments of Canadian coal into the province of New Brunswick totalled 360,000 tons, while the shipments from that province to other points in Canada amounted to 63,000 tons. Only about 10,000 tons of Canadian coal was shipped into Central Ontario during the year. Manitoba and the section of Ontario lying west of Fort William and Port Arthur received approximately 600,000 tons. Saskatchewan's receipts of Canadian coal were about 1,267,000 tons, while the shipments from that province for domestic trade were slightly under 100,000 tons. Alberta coal to the extent of 1,829,000 tons found its way to other Canadian provinces and 85,000 tons of British Columbia coal was also shipped for consumption in other parts of Canada.

### *Exports*

Exported Canadian coal amounted to 1,821,000 tons for the year, comprising about 1,000,000 tons from the western provinces and the balance from the maritime provinces. In spite of the strike the amount of Canadian coal exported during the twelve months ending December, 1922, was only about 160,000 tons less than in the preceding year. The exports during 1920 were 2,538,000 tons, and in 1919 amounted to about 2,000,000 tons.

### *Imports*

For the first time in many years quantities of coal were imported from Great Britain and in all about 874,000 tons was received, 710,000 tons of which was bituminous and 164,000 tons of which was entered as anthracite. The receipts at customs ports in Quebec of this coal from Great Britain amounted to 812,000 tons during the year while New Brunswick received 47,000 tons and the balance was equally divided between Ontario and Nova Scotia. Imports of coal from the United States amounted in all to 13,937,000 tons, comprising 11,255,000 tons of bituminous coal and 2,683,000 tons of anthracite coal. As compared with the records for the preceding year the imports of bituminous coal were 2,300,000 tons lower, and the imports of anthracite were 1,885,000 tons less. Comparison with 1920 figures would indicate an even greater shortage, as the imports of United States bituminous coal in that year were close to 16,000,000 tons and the anthracite imports came very near 5,000,000 tons.

### *Coal Made Available for Consumption in Canada*

The table shows the output, interprovincial movements, exports for foreign trade and imports for domestic consumption of anthracite, bituminous and lignite coal for each province in Canada and from the data given there has been deduced the amount of coal made available for consumption in each provincial division. For the whole of Canada the apparent consumption, or more properly, the coal made available for consumption in 1922 amounted to 27,200,000 tons and included 21,228,000 tons of bituminous coal; 3,083,000 tons of lignite; and 2,888,000 tons of anthracite coal. The principal coal-consuming province, as indicated in the table, was Central Ontario in which 9,849,000 tons was made available, including 1,716,000 tons of anthracite coal. In 1921 the same area was supplied with 11,543,000 tons and in 1920 with 13,331,000 tons. For Quebec the data given show that 4,450,000 tons of coal was made

available in 1922 as compared with 4,898,000 tons in 1921, and 5,327,000 tons in 1920.

The output figures given in the table were reported by the companies operating producing mines. The data on interprovincial shipments were also compiled from monthly statements sent in by the coal operators. The imports and exports items were compiled from data supplied by the Department of Customs, and in the case of imports, the figures given show the total quantity of coal imported from the United States during the year. Distinction must be made between this record and the figures given in the table of imports "entered for consumption." The tonnages "entered for consumption" represent only coal actually cleared from Customs for consumption in Canada. It often happens that large quantities of bituminous coal are brought into Canada but are not cleared from Customs until required for use, owing to the fact that there is a duty of 53 c. a ton on all bituminous coal, round and run-of-mine, imported. The exports figures show the quantities cleared through Custom ports during the year. Coal mined in one province is sometimes shown as exported from another province, a notable instance being that the bulk of coal exported from the province of Alberta is shipped through the Customs ports of Fernie and Cranbrook, in British Columbia, while some Nova Scotia coal is exported through the port of St. John, New Brunswick.

The coal made available for consumption computed from the data referred to above, is shown for each province. Separate totals have been made for the ports at the Head of the Lakes, and as much of the coal received at the Customs ports of Fort William and Port Arthur finds its way into Manitoba, a separate total has been made to include the data for Manitoba and Head of the Lakes.

From the data available it appears that in 1920 Canada produced 16.9 million tons, exported 2.5 million tons, imported 20.8 million tons, and thus apparently consumed 35.2 million tons. In 1921 when the output was 15 million tons, the quantity exported amounted to 1.9 million tons, imports to 18.1 million tons, and the apparent consumption was 31.1 million tons. The decline in the consumption of coal in 1921 was in conformity with the prevalent depression in the industrial world. For 1922 the output was 14.2 million tons, the exports 1.8 million tons, the imports 13.9 million tons from the United States and 0.8 million tons from Great Britain, so that the apparent consumption was 27.2 million tons. The decrease in every item was due to the strikes prevailing during the year, although the apparent consumption of 27.2 million tons was also partly due to depressed industrial conditions. The output towards the close of the year was decidedly improved.

Canada has the largest mileage of railway per capita in the world, with 4.42 miles for each 1000 inhabitants. Next comes Australia, with 3.54 miles; Argentine, 2.66 miles; United States, 2.50. Britain has 0.52 miles per 1000 population, which is characteristic of the Continent as well.

Mr. C. St. Clair Parsons, formerly of Toronto, has removed to England where his address is c/o Post Office Buildings, Middlesbrough. He has recently returned from a professional visit to Spain, Morocco and Algeria on behalf of the Northern Mercantile and Investment Corporation, Middlesbrough, for whom he is Supervising Mining Engineer.

# The Year in Ontario

By THOS. W. GIBSON\*

There is every reason to be gratified with the position of the mining industry in Ontario at the close of 1922. The year saw an increased output of the four metals of chief production—gold, silver, nickel and copper. Promising discoveries continue to be made, and capital, both from United States and England, is more readily interested. Prospects for 1923 are bright.

## Gold

Dealing first with gold, the yield for the year was about \$11,000,000 as compared with \$11,624,085 for 1921, an increase of over 10 per cent. Every one of the producers at Porcupine materially bettered its record for 1921. The output of the Hollinger was about \$12,000,000 as against \$9,051,276 in 1921; of Dome about \$4,000,000 as against \$2,200,261 in 1921, and McIntyre about \$2,000,000 as against \$1,827,761. The giant Hollinger has increased its holdings by the purchase of the Schumacher property which adjoins it and contains 160 acres. The price paid was \$1,600,000. At Kirkland Lake, two of the four leading mines exceeded the previous year's output. Tech-Hughes' production in 1922 was 575,000 as against \$322,919 in 1921; Wright-Hargreaves \$750,000 as compared with \$468,751; while Lake Shore's yield of \$480,000 and Kirkland Lake's of \$210,000 respectively were each a little under that of the previous year. These decreases at Kirkland Lake were due to the power being cut off for a month by the destruction of the transmission line in the great fire of October.

Taking the producing camps of Porcupine and Kirkland Lake, two features stand out from the experience of 1922.

1. Gold values increase with depth, at any rate up to the limits yet reached, say 2,000 feet at Porcupine, and 800 feet at Kirkland Lake.

2. In both camps bold campaigns of development are being undertaken on the strength of deductions drawn from geological structures.

Recent explorations, as for instance in the McIntyre, have obtained remarkable results below the present workings, and there seems at present no reason to doubt that the mines both at Porcupine and Kirkland Lake may, notwithstanding increased production, go on year by year, increasing the amounts of ore in reserve. This affords the best of reasons for increasing their capacity for turning out bullion. In consequence, extensions are being planned to plants in both camps, and there can be little doubt that the production during the next two or three years will rise to a still higher point.

Northern Ontario mines are fortunate in being situated close to hydraulic power. The falls of the rivers running down the slopes of the northern and southern watersheds are being pressed into use for operating mills and mines. The latter share these natural assets with the pulp and paper industry, and it would appear that in some localities there is not much power remaining undeveloped. It is understood that the Hollinger mine, which now crushes 4,500 tons of ore daily, would increase its capacity to 7,000 tons per day, if assured of increased power supply. Two new hydro-electric power developments are under way, one at Sturgeon Falls on the Mattagami river, to generate 6,000 or 7,000 horse power, and one at Indian Chutes on the Montreal river, of like capacity. Some of this power at both places should be available by February.

## Outlying Gold Properties

In addition to the established camps of Porcupine and Kirkland Lake, other gold areas are in various stages of

development. These include Larder Lake, where the Crown Reserve has located promising bodies of ore, and Night Hawk Lake, where the Night Hawk Peninsular is developing a good prospect, and building a mill. The deposits at Matachewan have been largely marking time, awaiting the advent of power, which Indian Chutes will supply. The finds at Lightning River are promising enough to warrant further expenditures, which doubtless will be made. Transportation and other difficulties have beset the group at Shining Tree, but work was done at White Rock and some other properties. The fine surface showings in this camp warrant further testing. North of Lake Superior, the Goudreau has been sunk upon, and will be given a chance to prove its quality; there are also favourable developments on several mining claims south of Schreiber. Further to the west, the old Mikado mine on

MR. THOS. W. GIBSON  
Deputy Minister of Mines

Lake of the Woods and the Foley on Seine River, both long idle, are being put in shape for renewed operation.

C. W. Knight, Associate Provincial Geologist, points out in his report on Lightning River, that in northeastern Ontario there are two main belts that contain the most important gold mines in the Province. These belts are roughly parallel and 25 to 40 miles apart. The northern belt runs from the Dome mine at Porcupine, eastward for 16 miles, the last known outcrop being in German township. Further to the eastward for 27 miles the rocks are almost entirely drift-covered. Then there outcrops another belt of the sediments, about nine miles long, in the Croesus gold mine area. Eastward again for 22 miles, drift intervenes, until on the Lightning River favourable conditions again occur, and promising discoveries of gold have been made. The southern band includes Matachewan, Kirkland

\* Deputy Minister of Mines, Ontario.

Lake and Larder Lake, and extends to and across the Quebec border line. Each of these bands follows a belt of Timiskaming sediments, consisting of conglomerate, greywacke and slate. Intrusions of feldspar-porphry and quartz-porphry have played a great part in the deposition of the gold. J. H. Curle, an eminent English gold mining engineer, sums up the geological situation by stating that the ore bodies are found where conglomerate meets porphyry, and gives his opinion that, "always excepting the Rand," northern Ontario will be the world's best gold belt for the next 20 years. Confidence in this diagnosis, which is concurred in by the geologists employed by the mining companies themselves, has led to large sums being spent in prospecting the eastward extension of Kirkland Lake. So far no Hollingers or Domes have been found, but gold ore has been located in a number of places and it may well be that fortune will smile on some of the seekers for gold in eastern Kirkland.

#### *Silver*

The day of silver production is by no means over in Ontario. On the contrary, the output of the Cobalt camp for 1922 was about ten million dollars in value, as compared with \$8,412,059 in 1921. The average price of silver for the year was a little higher than in 1921, when it was 65.65 cents per ounce. The natural processes of consolidation in a camp of the age of Cobalt are under way, the smaller companies being absorbed by the larger ones. Mining Corporation, for instance, has acquired a large acreage in the neighborhood of the Keeley mine, having taken over among other claims those of the Frontier Mining Company and the Crompton property. Coniagas has leased the Beaver mine and the Badger, Prince and Davis properties adjoining. O'Brien, Limited, whose plant was destroyed by fire, has bought the mill of the Bailey property and will send its ore thither by aerial tramway for treatment.

South Lorrain is attracting much attention by reason of the remarkable recrudescence of the Keeley mine and the excellent results obtained by the Mining Corporation on the adjacent claims. The Keeley mine broke the Farmers' Bank and put its president in jail. When the bank's assets were sold, the Keeley was purchased for a song. J. Mackintosh Bell, manager of the English company that acquired the mine, sized up the mine's geological conditions and induced his company to sink. The result was the Woods vein proved to contain remarkably rich ore. The Keeley production for the year may be put at about \$800,000.

Nipissing, the leader of the Cobalt camp, maintains its position well, its production being a little under 4,000,000 ounces for the year. Mining Corporation comes next with 1,750,000 ounces. O'Brien and Coniagas follow with over 1,000,000 each. In Gowganda the chief producer remains Miller Lake-O'Brien, but its neighbor, Castle-Trethewey, has found good ore and may erect a small mill in 1923. Favourable developments have also taken place on Everett Lake.

Discoveries of argentiferous galena on Red Lake in the district of Patricia, north of the English river, created considerable interest last autumn. The veins appear to be narrow, but assays show high values in silver. The area is likely to be thoroughly prospected when the snow leaves next spring.

#### *Nickel-Copper*

The pace by which nickel mining is returning to normal quickens. The International Nickel Company begun work in the Creighton mine in August and blew in two converters at the Copper Cliff smelter, adding a third later in the year. The refinery at Port Colborne was opened on 1st. May. Henceforward, all nickel refined by this com-

pany will be produced at the Port Colborne plant, the works in New Jersey having been dismantled, the machinery sold, and the buildings torn down. Some of the nickel matte will continue to go to Huntington, West Virginia, for use in making Monel metal, the now well-known alloy of nickel and copper, whose production does not require separation of these metals from one another and which is coming increasingly into use for a large variety of purposes where toughness and resistance to corrosion are required. The Mond Company emptied its matte storage yards for the first time since the armistice. In fact, this company never actually stopped working, and is prepared to meet its share of the reviving demand for nickel and nickel products. The American Malleable Nickel Company has opened a plant at Clearfield, Pa., for the manufacture of malleable nickel, using the product of the Mond company. The Murray mine and Nickelton smelter of the British America Nickel Corporation, Limited, where idle during the whole year, but part of the refinery at Deschenes, Quebec, was in operation for a portion of the time. The nickel contained in the matte produced by the companies during the year was about 8,500 tons, an increase over 1921 of 1,000 tons. The copper output for the year, practically a by-product of nickel, was, say, 6,200 tons, also an increase over the production of 1921 by 1,000 tons.

#### *Iron*

The production of pig iron fell off during the year by over 100,000 tons, the output for the first nine months being 291,926 tons, as compared with 393,303 tons for the corresponding period in 1921. Very little Ontario iron ore is now being smelted, either in or outside the Province. A committee of experts, appointed by the Minister of Mines, Ontario, is investigating the Ontario iron ore situation, with special reference to our low-grade deposits. Beneficiation of similar ores, now being practised at Babbitt, Minn., seems to point the way for similar operations in Ontario. In some quarters hopes are entertained that new or old processes of treating by electricity will solve the problem of how to produce pig-iron in Ontario from Ontario iron ore.

#### *Non-Metallics*

The minor branches of the mining industry were on the whole depressed during the year. Not much feldspar was produced, and little graphite or mica. Tale is doing fairly well, but the mining of iron pyrites has practically ceased. A good demand was experienced for cobalt oxide, and refineries that were stocked with residues are now having a chance to market their accumulations. Towards the close of the year a decided increase of interest was exhibited in arsenic. Ravages of the boll-weevil in the cotton fields of the southern United States threaten the entire destruction of that crop. The approved method of checking this pest is by the use of calcium arsenate. Arsenic is produced in the United States as a by-product only, being recovered in the refining of other metals. The total production is quite insufficient for home needs, and arsenic ores in other quarters are being eagerly sought after. The price of the refined product has gone up to 12 cents per pound, and even higher prices are looked for, unless the United States government should establish a maximum. The enhanced demand has accrued to the benefit of the silver refining companies treating the Cobalt ores, which for many years have been the source of all the arsenic produced in Ontario. Owners of mispickel deposits in Eastern Ontario may now also have an inning.

Building operations in the cities were quite brisk throughout the year, and the demand for construction materials such as bricks, lime, sand and gravel, was correspondingly great. The value of buildings erected in 1922 showed an increase of about 40 per cent. over 1921.

# Quebec Mineral Industry in 1922

By THEO. C. DENIS \*

Although general industrial conditions are yet far from normal, the mining industry in Quebec has gradually improved during the year 1922, from a low ebb in January to a much better condition in December. The curve has shown a pretty continuous ascending tendency, whereas during the preceding year it had been decidedly downward.

Except for one or two of the principal items, the Quebec Bureau of Mines collects the mineral statistics for the calendar year only, so that it is too early to have any basis, other than general data observed throughout the year, to forecast the figures of production of the past twelve months; but they will show an appreciable increase in the value, and a substantial growth in the quantities, the value increases will be relatively less than the tonnages owing to the lower prices that prevailed.

## Asbestos

For many years Asbestos has been the largest individual item on the list of Quebec's mineral production, exceeding at times one half the value of the yearly total production, and the year 1922 will not be an exception. That the Quebec Asbestos industry has felt keenly the depression in the industrial conditions is shown by the fact that the production of this mineral fell from 14 $\frac{3}{4}$  million dollars in 1920 to 5 $\frac{1}{4}$  million in 1921. During the first months of 1922 the decline still continued and the bottom of the wave seems to have been reached last April, when a very slight improvement began to make itself felt. The majority of the asbestos operators had to suspend mining and milling during the winter and the spring, and the few mines that continued to produce did so at a greatly reduced capacity. It is a remarkable fact that at the end of the year 1921 the value of the stocks of asbestos remaining unsold considerably exceeded the value of the shipments during the year. It was especially the long fibre qualities that were slow to move, and the producers had to reduce the prices of the higher grades, proportionately more than the mill-stock qualities. In fact, the average price of the crude No. 1, which for the year 1921 was \$1,300 a ton, had to come down in November 1922 to \$700, the longest fibre bringing only \$900.

There has been a general tendency and impression to ascribe the slump in the demand for the Canadian Crude fibre to the inroads made by the Rhodesian asbestos, in markets that have, in the past, been exclusively supplied by the Quebec fibre. While there is no doubt that the Shubanie and the Victoria asbestos are becoming serious competitors of our asbestos in the United States market, the official figures of shipments of South Rhodesian material during the first seven months of 1922 show a depression much more marked than in Canada. From January to August 31st., 1921, South Rhodesia exported 17,069 tons of asbestos, and for the corresponding 1922 period this had fallen off to 7,365 tons.

The figures of shipments of Quebec asbestos in 1921 were 87,475 tons, valued \$5,199,789, and it is probable that for 1922 the tonnage will show an increase of 35 p.c. and the value 20 p.c. on these figures.

\* Supt. of Mines, Quebec.

It is interesting to note that the government has reduced the royalty on asbestos, from 5 p.c. on the gross value of the asbestos shipped, to 2 $\frac{1}{2}$  p.c., thereby cutting it in two. The order-in-council to this effect was passed on October 21st 1922, and is retroactive to January 1st. 1922, so that on all asbestos produced from January 1st. the new rate will apply.

## Copper, Lead and Zinc

The mining of metalliferous minerals, unfortunately, does not show signs of reviving. It has been essentially inactive throughout the whole year, as regards production. All our mines of sulphur-copper ores remained idle, whereas four years ago they were producing at the rate of six to seven hundred tons a day. One of these, the Weedon mine, has a record to be proud of. From 1911, when it began shipping copper-bearing pyrite, until 1921 when it was shut down, this mine produced nearly 600,000 tons of ore, representing a total value of 5 $\frac{1}{2}$  million dollars.

There has been no mining of lead-zinc ore, the Montauban mine having remained closed all year, in spite of the marked improvement in the market for these two metals. The Federal Lead and Zinc Company continued the development of their Gaspé property and the construction of the waggon road, 45 miles long, to connect the mine with the railway at Cascapedia station.

## Gaspé Promises Much

That the Gaspé peninsula contains metalliferous deposits that will eventually give good account of themselves, received further corroboration by the staking of several claims for copper in the region of the headwaters of the York river. An officer of the Quebec Bureau of Mines made a short examination of this region last summer and found that the geological conditions are favourable to the presence of deposits of copper of workable size. The rocks are porphyries, volcanic tuffs, trap rocks and granites which occupy a very large area, to the exclusion of all other rocks. The mineralization is widespread, as evidenced by the numerous green stains of carbonates of copper. A series of samples taken in various places gave assays varying between 2 and 10 p.c. copper. These new discoveries, added to the known presence of native copper and sulphides in Matane; the deposits of lead and zinc of the Cascapedia river; the zinc-lead-copper occurrences of Christy township; the copper showings of Matapedia township and of Port Daniel township; the serpentine of Weir township and of the Albert mountain massif, show that the whole of Gaspé peninsula, which constitutes the terminal area of the Appalachian mountain system and embraces a region which has been extensively disturbed by mountain building forces, intense volcanic action and igneous intrusion, offers a promising and almost untouched field to the prospector.

## Chromite and Molybdenite

There was practically nothing done in chromite mining, although in November there were rumors that the Belanger mine, at Coleraine, was to be reopened by the United States Ferro-Alloys Corporation, who bought the property after the liquidation of the J. V. Belanger Chrome Mining Company. The future of the Quebec

chromite industry is very unpromising. Our chrome ore cannot compete, for costs, with African or New Caledonian mines.

A renewal of interest is apparent in the deposits and occurrences of molybdenite throughout the province, owing to progress made in the metallurgy of molybdenum during the last twelve months. The deposits on the north shore of the Ottawa river, as well as the very promising occurrences in the region of Kewagama lake and Harricana river, in North-western Quebec, could furnish a steady supply of molybdenum ore. Molybdenum steel is being used in special parts of automotive machinery, such as axle-shafts, drive-pinions, steering-gears and knuckles.

#### *Non-Metallic Minerals*

The other non-metallic minerals, feldspar, mica, magnesite, kaolin, whose production during the preceding two years had suffered greatly, have experienced a renewal of activity, and the production for the past year will be considerably in excess of the figures for 1921. The feldspar of the Buckingham district, more particularly of Derry township, is acquiring an enviable reputation and the demand is growing greatly. There are at present three deposits that are shipping actively. This feldspar is very pure, with practically no quartz. An idea of the grade may be formed from the fact that analyses of carload-lots run up to 13½ p.c. potash and 1½ to 2½ p.c. soda. It may also be mentioned that the St. Lawrence Feldspar Company is at work developing the large feldspar deposit of the Mingan seigniory, on the north shore of the Gulf of St. Lawrence. This company has begun the construction of a wharf, which will permit shipping by vessels of a large tonnage.

The production of mica in 1921 had been the smallest recorded since the Quebec Bureau of Mines began to collect statistics of mineral production, some twenty-five years ago. From a value of \$282,000 in 1920 it fell to \$42,000 in 1921. But in the spring of 1922 the demand improved greatly, and although the production this year may not be a record, it will be approximately normal. The principal mica-producing district of the Province is the region that comprises the basins of the Gatineau and Lièvre rivers, two tributaries of the Ottawa. There are, it is true, mica deposits, such as in the vicinity of Quebec city and in the lake St. John region, but the Lièvre-Gatineau district alone supplies more than three-quarters of the Canadian production of mica.

The China-clay industry of Amherst township took a long step forward this year. Underground development work at the St. Remi mine of the Canadian China Clay Co., blocked out a considerable body of white kaolin which is being mined by the caving method. This material, washed of all sand, filter-pressed and dried, is perfectly white and finds a market as a paper filler; in the paint industry; and in all industries needing a white filler. In October the mining method was being altered to permit of a larger output at a reduced cost. It was then expected that the production would soon be increased to 30 tons per day of refined kaolin.

Another kaolin deposit was being opened up one mile to the south of the St. Remi mine by Mr. J. C. Broderick, who has a washing plant under construction.

The production of building and road materials was very active throughout the whole year. Construction, of buildings and of roads, created a keen demand for brick, stone, lime and cement, which will probably show an increase of 30 p.c. in value over the 1921 production which was 9¾ million dollars.

#### *Prospecting for Gold*

A review of the mining industry of the year, would not be complete without a short reference to the prospecting activity which prevailed throughout the whole summer and fall in the north-western part of the province, both in the district immediately east of the Ontario-Quebec line, and also in the region of the headwaters of the Harricana river. Beginning in March, this rush developed in the extension, into Quebec, of the mineralized belt which in Ontario includes the two gold camps of Kirkland lake and Larder lake. The main centers of claim-staking in this belt are lakes Tremoy, Héré and Pelletier, in Rouyn township; lake Fortune in Dasserat township, and lake Renaud in Boischatel township. The discoveries made at all these places are said to be extremely encouraging, and in these three townships there are at present some 200 claims staked, of a total area approximating 30,000 acres.

In the Harricana district three American syndicates are now at work carrying on shaft-sinking and diamond-drilling on three of the more promising properties of the region, viz, the Martin mine, the Stabell claims, and the Foisy-Kengrow claims, all in Dubuisson township.

In conclusion it may safely be stated that in the year 1922 the Quebec Mineral Industry took a long step towards returning to normality, and it is probable that the value of the products of our mines and quarries will show a substantial advance on the figures of 1921, which totalled 15½ million dollars.

#### LEAD AND ZINC IN UNITED STATES IN 1922

During 1922 there was produced in the Mississippi Valley lead-zinc district 256,000 tons of lead, and in the western states, 208,000 tons of argentiferous lead, a total of 464,000 tons, which is an increase of 54,300 tons over 1921, according to the United States Geological Survey.

Zinc to the amount of 447,000 tons was produced, against 256,746 tons in 1921. Of this the Joplin district accounted for 254,000 tons, and the east and west the remainder in equal proportion.

The export and import trade in lead and zinc is small in proportion to the purely domestic production and consumption. Last year 52,000 tons of lead bullion was imported from Mexico, while 28,000 tons of zinc from United States ores was exported.

The average price for lead in New York during the year was 5.7 cents a pound, as compared with 4.5 cents in 1921. At the end of the year the price was 7.25 cents. Zinc prices at St. Louis averaged 5.7 cents a pound, against 5.0 cents in 1921, and rose to 7.35 cents at the middle of November, being 7 cents at the end of the year.

Next to the United States, Mexico is the largest oil-producing country in the world. These two countries produce at present nine-tenths of the world's petroleum. One-fifth of the whole area of Mexico is underlain by petroliferous measures.

# Coal Mining in Nova Scotia in 1922

By F. W. GRAY\* M. I. Min. E.

The tendency of coal production in Nova Scotia is shown by the following table:

|                      | 1913      | 1919      | 1920      | 1921      | (Estimated)<br>1922 |
|----------------------|-----------|-----------|-----------|-----------|---------------------|
| Output at N. S.      | 8,103,404 | 5,390,196 | 6,137,156 | 5,741,928 | 5,561,000           |
| Mined by means of    |           |           |           |           |                     |
| British Empire       |           |           |           |           |                     |
| Steel Corporation    | 1,204,410 | 3,000,720 | 3,429,286 | 1,913,688 | 1,781,000           |
| Mined by other       |           |           |           |           |                     |
| methods              | 881,694   | 789,476   | 1,007,870 | 1,912,410 | 1,800,000           |
| Percent mined by     |           |           |           |           |                     |
| Steel British Island | 15        | 55        | 55        | 33        | 31                  |

The year 1913 was the one that saw peak production of coal in Nova Scotia, as it saw peak production of many other minerals in Canada. The year 1922, in contradistinction, will in all probability prove to have been the one of lowest production for a number of years to come.

1922 was in all respects a poor year, so far as the fundamental conditions of business are concerned, and the brisker demand that developed for coal in the late summer of 1922 was not so much the result of real business improvement in Canada, as a reflex of the five months' strike of the United Mine Workers of America in the United States. The business outlook is still clouded, and there is no general agreement among those who attempt the forecasting of business conditions as to what the immediate future holds. The basic weakness of industrial conditions is shown by the rapidity with which the shortage of coal resulting from the five months' strike in the United States has changed to a condition where substantial stocks of coal are reported at producing points, simultaneously with very partial and irregular work at the bituminous mines. Any absolute shortage of bituminous coal at consuming centres in the United States and Canada is at this date a result of transportation congestion and car shortage.

## A Broken Year

The coal mines of Nova Scotia in 1922 did not achieve anything like capacity production. For the first six months of the year there was a total lack of demand, and the effect of this on production of coal was intensified by the policy of the miners' leaders in advocating restriction of production by "striking on the job." The three weeks' strike of the United Mine Workers in August, and the damage done to the producing capacity of the mines by the withdrawal of the maintenance forces and physical opposition to their replacement by officials, further and very considerably diminished the output for the year.

In November, a sleet storm of great destructive effect disorganized the power lines and all wire communication at the collieries in the Sydney Field, and complete repairs cannot be made until the spring.

The cumulative result of these hindrances to production has been to make 1922 a year of memorably low coal outputs, and one that in all likelihood will mark a low point in the current history of coal mining in the Province.

With 1923, it is believed, will commence a steady climb of outputs to figures comparable with pre-war tonnages, although it is not possible to forecast the date when the maximum production of 1913 will again be attained. It can hardly fall within the nineteen twenties.

## St. Lawrence Trade Regained

The most encouraging feature of the year was the large-scale resumption of coal shipments to St. Lawrence ports,

\* Headquarters staff, British Empire Steel Corporation.

which reached approximately 1,400,000 tons, or seventy percent of the maximum seasonal shipments previously attained. Shipping was prolonged in the St. Lawrence until the latest date as yet attempted, the S. S. "Rosecastle" leaving for Levis from Sydney on November 29th., and leaving that port for Sydney on the morning of December 10th. It is understood an attempt will be made with the assistance of ice-breakers to bring about an early opening of navigation from the port of Sydney in the spring of 1923. A successful demonstration of the possibility of prolonging the season of open navigation in the St. Lawrence River and Gulf is of much importance to the Nova Scotia trade, which has in the St. Lawrence ports its natural and most important market.

Another encouraging feature of the year has been the use of a substantial quantity of sized by-product coke as a domestic fuel and its substitution for anthracite. The demand for this cleanly, hot fuel is much greater than the supply, the coke so far used having been a by-product of the screening of coke primarily intended for blast-furnace uses; but it has demonstrated the entire suitability of sized coke as a satisfactory substitute for anthracite, and this is doubtless but the beginning of much greater things.

## Continued Shortage of Skilled Miners

The chief deterrent to production of coal is still the shortage of men actually mining coal at the working faces. While the aggravated shortage of the war years has been partially remedied by augmentation of the numbers of men

MR. F. W. GRAY

at the face of the coal, there is still a grave shortage of this all-important class of workers, accompanied by a corresponding shortage in the outputting of coal, the shortage of miners being the cause and the shortage of production the result. This statement is unfortunately not as elementary as it may appear, nor is the remedy quite so simple

as the diagnosis. Until the number of face-workers is restored to pre-war figures the production of coal cannot attain to pre-war tonnages. This is the real problem of coal production in Nova Scotia.

#### *Development of the Mines*

Capital expenditure on the development of new mines and the winning of new coal areas has been limited during the past ten years, but coal-mining is an industry that cannot progress unless the process of mining coal is accompanied by a concurrent process of opening up new territory. Therefore the resumption of capital expenditures on a substantial scale may be forecasted as not likely to be long delayed. The original sin of coal operators the world over is inadequate provision in cost-accounting for the new expenditures that are required to maintain a wasting asset, and in Nova Scotia, as elsewhere, the price at which coal was sold to customers in past years has not always included a sufficient margin of profit over labor and materials charges to represent a real profit when the cost of new mines and capital redemption has been counted in.

The Dominion Coal Company is sinking an important new shaft to the Phalen Seam between the existing Nos. 1 and 2 collieries. This shaft will win a submarine area tributary to both collieries named but too distant from No. 1 and 2 shafts to be economically won to these points. The new shaft will be equipped with modern hoisting machin-

ery and the latest type of surface erections. The underground layout will be designed to handle a large output, gathered from a very extensive area, and, when completed, this new mine will, it is expected, become a producer of first-rate importance with a long life before it.

This Company is also developing the Emery Seam in the Glace Bay district, by a slope opening. Electrically operated coal-cutters of the shortwall chain-cutter type are being used in this mine, the seam being well adapted for electrical cutters.

At Springhill Mines, two new slope openings, known as Nos. 6 and 7 Collieries, are being rapidly developed to important producers. The old boiler plant at Springhill, a very out-of-date unit, is being replaced by a more efficient plant. During November the Springhill group of mines produced almost 50,000 tons, a figure that has not been reached for seventeen years by a single month's output.

The Acadia Coal Company's mines are producing at a high rate, the daily production reaching 2,500 tons on good days.

The settlement after the U. M. W. of A. strike in District 26 in August resulted in the signing of an agreement which covers the whole of 1923, and from this point of view there should be a year of settled conditions ahead. Next year should be one of recovery from depressed conditions and of moderate production.

## Metalliferous Mines of Nova Scotia during 1922

By THOMAS BEVERIDGE\*

On going to Nova Scotia some eleven years ago, having previously read many of the geological reports on the province, I was surprised beyond words to find that so little was being done in the development of the mineral resources. The reports of Drs. Faribault, Gilpin, Fletcher and others speak in the most glowing terms of the mineral wealth, and many who have visited the province would be as much astonished as I was at the lack of a systematized plan in the development of what is one of its richest assets. Hitherto mining has practically been confined to the production of gold, and this has been done in what might well be termed a blindfolded manner; and to-day while more prospecting and development is noted in almost every known gold-mining district, Nova Scotia is falling far short of what might reasonably be attained. If the reports of these gentlemen of undoubted standing are true (and I have every reason in saying they are), what is wrong? This question in my opinion can be answered by one word, namely—development. While geological information is exceedingly helpful to the mine owners and engineers in the development of their property its usefulness amounts to nothing when the practical phase of the question is neglected, and that is the case in Nova Scotia.

During the past summer I made a tour of inspection of the mines, other than coal, and quarries for the Provincial Government of Nova Scotia and I visited every known gold mining district, and with the opportunity afforded me I made a very close study of the actual condition of affairs and of the possibilities that could reasonably be expected with more up-to-date machinery and a modern system of mining and milling. That the loss of gold over the plates is the chief cause of the present condition of the gold mining in Nova Scotia, is an undoubted fact; and when I place this loss in most cases at from 30 to 50 per cent, I think it can clearly be seen why the gold industry is in the

position we find it now. The following assays will prove to a certain extent the truth of my contention:—The first, made by the Anaconda Copper Mining Co. on August 12th 1922, of concentrates taken from the tailings of the Montague Gold Mining Coy's dump, gave gold, 2.16 oz. per ton; Arsenic 43.7 per cent. The second, made by the General Chemical Coy. in September, 1922, from the same dump, gave gold 3.18 oz. per ton; Arsenic 36.5 per cent; sulphur 25 per cent. Another striking proof was clearly demonstrated by a small company in another district who put through their stamp mill 10 tons of old tailings with a recovery of three dollars per ton, leaving, no doubt, values still in the tailings.

With the high percentage of arsenical iron and other gangue matter in the quartz, and with it a large percentage of barren slate, the percentage of pay ore is materially reduced. I fail to see how it is possible with the present system of amalgamation and no treatment of the tailings to obtain any better results than have been secured in the past. There is no doubt in my mind that the high percentage of arsenical iron, preventing amalgamation, carries the gold over the plate, and is the root of most of the difficulties. Another difficulty must not be lost sight of—that with the large quantity of slate crushed, containing as it does a large percentage of tale which cakes on the plate necessitating a big flow of water, values are lost because of the undue force of the stream of water.

With the adoption of a suitable system of extraction (and I cannot at present see that it is in any way unsurmountable,) and with the development of cheap power, of which the Province has abundance, gold mining should take a fresh lease of life and prove a profitable industry. It is most interesting to note that the Mines Department at Ottawa are at least making some effort to try and assist this most important industry by making tests of all the tailing dumps in the Province, and by so doing to indicate an efficient system of extraction. I have no hesitation in saying that if this had been done long ago and a solution

\*Consulting mining and electrical engineer, New Glasgow, Nova Scotia.

found. I see no reason why the Province of Nova Scotia would not now be holding its own with any part of Canada as a gold producer. That there are great possibilities in different parts of the Province, I feel, will be proved in the near future. The neglect in the development of the large bodies of low-grade ore in favour of the narrow high-grade veins has done much to retard development.

During the past year only one company has been working regularly, viz., The Sherbrooke Mining and Power Corp., Goldenville, Guysboro County. They have a large body of low-grade ore and when sufficient development work is done to increase their output a reasonable profit should be shown. Having their own hydro-electric power I am told by the manager that they can mine and mill at a little under \$3. per ton. There are quite a number of other properties that have been producing in a desultory way, but the lack of systematic modern development has prevented any notable result.

An increase of about 300 oz. of gold over 1921 is encouraging but in 1923 a much larger output can reasonably be expected. The mines that will, it is hoped, start producing during the year will be the Montague, Cochran Hill, Tangier, Beaver Dam and Nova Scotia Mineral Reduction Coy. At the Montague and Cochran Hill a new flotation process patented by Messrs. Harr Bros. will be installed and should go far to surmount the milling difficulties. The concentrates from these mines will be shipped to the United States for treatment. The Montague has been a good producer in the past and with the solving of the milling problem good results should be shown. Cochran Hill has a 75 foot zone of low-grade ore known as the Mitchell belt. Samples have lately been assayed that have given surprising results. The Tangier also has a good re-

cord but I cannot say they will meet with the success they should while using the present amalgamation process and no treatment of tailings. Beaver Dam and the Nova Scotia Mineral Reduction Corp. are adopting a semi-roasting system, but at the date of my visit no definite plans had been made as to what further method would be used after crushing and roasting.

The development of the Sheet Harbor hydro-electric power by the Government for the supplying of power to New Glasgow and surrounding towns should do much for gold mining, as the trunk lines pass through and near many well-known mining districts such as the Fifteen Mile Stream, and should have a tendency to increase activity in these several camps.

Special mention should be made of the Malagash salt mine, operated and owned by Messrs. Chambers and McKay. A shaft has been sunk to a depth of 200 feet and large bodies of salt have been opened up by driving and drifting. It is pleasing to note that there is a marked improvement in both whiteness and chemical quality as the lower depth was reached. At a conservative estimate there is about twenty five millions of tons of salt in the deposit.

In the case of other minerals such as iron, copper, etc., only prospecting is being done at present.

In conclusion I may say that gold mining in Nova Scotia depends on the following, (1) suitable and cheap means of extraction. (2) up-to-date machinery. (3) the use of cheap power, of which the Province has abundance in almost every district. (4) a better system of mining and management. With due attention to the above I have no hesitation in saying that Nova Scotia will in a few years take its place as a large gold producer.

## Mining In British Columbia During 1922

By ROBERT DUNN \*

The value of the mineral output of British Columbia for the year 1922 is estimated to be \$32,167,463, as compared with \$28,066,641 in the previous year, an increase of \$4,100,822, as announced by Hon. W. M. Simon Minister of Mines. The feature of the 1922 production is the increase in the gold and silver values, the former amounting to \$4,116,816, which is \$1,079,462 better than in 1921, and the latter totalling \$4,034,154, which is \$2,442,953 in excess of the previous year.

Credit for this lies to a great extent with the Premier Gold Mining Company, of the Portland Canal Mining Division. The lode gold and silver taken from the Cassiar District, of which Portland Canal is a part, are estimated to be: gold, 170,200 ozs., silver, 4,816,000 ozs. The greater part of this, in fact practically all of it, came from this great mine.

A telegram from our British Columbia correspondent states that Mr. H. A. Guess, president of the Premier Gold Mining Company, has announced that the company will pay a dividend on January 3rd of \$750,000. This is 15 per cent. of the \$3,000,000 capital, and brings the total paid to shareholders up to \$3,150,000. If this is a New Year's resolution, to be continued throughout the year, the Wonder Mine of British Columbia cannot fail to stimulate in that province an interest in mining development that is already highly satisfactory. — Editor, C. M. J.

\* Department of Mines, Victoria, B.C.

Placer gold output also shows an increase the total being estimated at \$297,000, an increase of \$63,800. Marked interest has been taken during the year in the placer fields. Hydraulic and dredging operations, actual and projected, are multiplying. While the old camps of the Cariboo and Atlin are not more than holding their own, new possibilities are being manifested. Mr. Sloan directs attention, in this connection, to the Cedar Creek field as proving that the historic Cariboo has not yet given up all her riches. J. D. Gallowsay, the resident government mining engineer, emphasizes the importance of this discovery from which some \$73,000 worth of gold was taken during the season notwithstanding that both water and equipment were limited. The proving of one rich high level channel, such as that upon which the present Cedar Creek diggings are located, may lead to the finding of more ground of a similar character in the Cariboo. Certainly it is very encouraging and undoubtedly will result in more intensive prospecting, along somewhat different lines from what has taken place in the past.

In regard to precious metal production it is to be noted that the Belmont Surf Inlet Mines Ltd., Princess Royal Island, have added quite materially to the gold output and that recent developments, in point of ore reserves, are said to be satisfactory. The Nickel Plate Mine, Hedley Mining Co., has done little while the Rossland Camp, which in former years was the backbone of the lode gold industry, has not been producing. The latter centre, however, is expected soon to be as active as before. The output of silver has been swelled by contributions from many comparatively

small, but potentially important, mines of the Slocan and other parts of the East Kootenay, where there has been a revival that augurs well for the future.

Only one of the base metals shows a decline as against 1921, viz., copper. The value of the output is estimated to be \$4,642,060, a drop of \$837,564. The reason for this is that the Britannia Mining Co., Howe Sound, has not been shipping. The destruction of the plant by fire and other difficulties forced the Company to concentrate on development and reconstruction. The prospects are that it will be ready to resume production early in the New Year. Under the circumstances it is gratifying that the total value of the provincial production was so well maintained and the explanation is to be found in the achievement of the Granby Consolidated Mining and Smelting Company, whose output is placed at 29,690,000 lbs.

Lead and zinc outputs have increased, the first by \$790,542 and the last by \$455,543. The silver-lead-zinc ores of the Kootenays are responsible, the bulk of the two latter metals coming from the ores of the Sullivan Mine, Kimberley. The new electrolytic method of treating zinc ores at the Trail Smelter, Consolidated Mining and Smelting Co., has given courage to many independent operators and the new concentrator at Kimberley, now under construction, strengthens the conviction that conditions have permanently improved and that the immediate future of the mining industry in eastern British Columbia is unusually bright.

The coal production will approximate 2,559,414 tons, valued at \$12,797,070, an increase of \$377,095. Coke is estimated to drop from 59,434 to 40,837 tons, a decrease in value of \$130,179. These figures are considered gratifying in view of the fact that the Crow's Nest field was idle for several months and also for the reason that the collieries of the Province, and particularly those of Vancouver Island, have had their market invaded by imported fuel oil. Mr. Sloan asserts that one million tons of locally produced coal is being displaced annually by these importations and that, if the industry is to grow as it should, there will have to be a reduction in the amount of this fuel consumed in the Province.

Following are the details of the preliminary estimate of mineral production for 1922:

# NORTH EASTERN MINERAL DISTRICT

The year 1922 has been an encouraging one for mining activity throughout the North-eastern District, and it would seem that the depression of the past two years has definitely passed. The lode mineral production is as yet small but the development work done this year gives substantial promise of a largely increased output in the future. The great need of the district is capital to test the numerous mineral showings held by prospectors, and it is to be hoped that the successful work this year will encourage others to take up promising properties.

A marked revival in placer mining has been evident in the Cariboo and Quesnel Divisions. The important discovery of Cedar Creek camp (discovered in the late fall of 1921) has aroused considerable interest and during the summer there was an influx of prospectors. Cedar creek proved during the year to be an important find, both in itself as a bonanza, and as an indicator of the possibilities of that section of the country.

Much Keystone drilling of placer gravels has been carried out in the Cariboo during the year, with satisfactory results in several places. The hydraulic mines of the Cariboo had a poor year, due entirely to an insufficiency of water supply caused by an unusually dry season. Rains late in the fall enabled some fall clean-ups to be made but the hydraulic gold production was much less than would have been the case under normal water conditions. Notwithstanding this the placer production of the Cariboo District was at least double that of 1921.

The coal-fields of the North-eastern District have not as yet made much production. A small tonnage (700 tons) was again mined from the Betty mine near Telkwa. Diamond drilling of the Copper River Coal Company's property was carried out during the season, and it is believed that the results were satisfactory.

The following table gives a rough estimate of what the mineral production of the year will be:

|                              |           |
|------------------------------|-----------|
| Placer, gold . . . . .       | \$140,000 |
| Lode, gold, ounces . . . . . | 40        |
| Silver, ounces . . . . .     | 32,500    |
| Lead, pounds . . . . .       | 50,000    |
| Zinc . . . . .               | 75,000    |

## PRELIMINARY ESTIMATE OF MINERAL PRODUCTION FOR 1921 AND 1922

|                                                | Production 1921 |              | Estimated Production 1922 |              |              |           |
|------------------------------------------------|-----------------|--------------|---------------------------|--------------|--------------|-----------|
|                                                | Quantity        | Value        | Quantity                  | Value        | Increase     | Decrease  |
| Gold, Placer . . . . . oz.                     | 11,660          | \$ 233,200   | 184,800                   | \$ 297,000   | \$ 63,800    | .....     |

| Total Production . . . . .                     | .....           | \$28,066,641 | .....                     | \$32,167,463 | \$ 4,100,822 | .....     |

Following is a brief summary of the more important lode-mining developments in the District during the year:

**COSSA-MISSA MINE, DOK.**—The crosscut tunnel on this property was continued and at a distance of 400 feet from the portal the "Blind Vein", which has previously been developed by a winze from the upper crosscut tunnel, was struck. Where cut, this vein has a width of from 10 to 12 feet and carries mineralized bands on both walls. The minerals are chalcocite, bornite and free gold, and it is expected that a width of from four to five feet will make good milling ore. Drifting on the vein is to be carried on all winter.

Prospectors in the Usk section were busy all summer developing their properties and some of the showings have been considerably improved.

**SILVER STANDARD MINE, HAZELTON.**—This property was re-opened in January and operations were continued for about three months, when the property was again closed down. The work consisted of taking out ore and milling it, some 500 tons being milled. The property is now in the position that further development is required and it is believed that this may soon be arranged for.

The copper properties on Rocher Deboile mountain were not re-opened during the year.

**FIDDLER PROPERTY, DORREEN.**—Development of this property was carried out during the summer with a small force and is being continued. Plans are now being prepared for the erection of a small mill on the property and it is expected that this work will be carried out next year.

**HUDSON BAY MOUNTAIN, NEAR SMITHERS.**—Important mining operations have been commenced on Hudson Bay mountain by Mr. J. F. Duthie of Seattle. Three groups are now under option to Mr. Duthie and steady work is being carried out on two of them under the superintendency of Mr. John R. Turner. The Mamie group, which was the first one acquired, carries good values in gold and zinc and is now being developed by a 1,000 foot crosscut tunnel; this tunnel is now in about 300 feet and is expected to reach the vein sometime next spring. The Henderson group adjoining the Mamie was secured in July and by the end of October it is reported that about \$20,000 worth of ore had been taken out. This vein carries galens, zinc blende and grey copper; this last mineral is very rich in silver and analyses of the pure mineral show that it contains about 25% silver and is properly classified as freibergite. Besides the high-grade hand-sorted ore that has been taken out, much of the material on the dumps is good mill feed. The vein is being developed by drift tunnels and in addition open-cutting and stripping of the surface have been done. Altogether the showing is a very promising one. The Hanna group was acquired in the fall and with the exception of a little surface prospecting no development has yet been done. The veins on this property carry silver-lead-zinc minerals. It will probably be necessary to develop this property by sinking and so it has been impracticable to start this work until next spring.

Gasoline-driven compressors have been put in on the Mamie and Henderson properties, camp buildings have been erected and much preliminary work done. From 25 to 30 men are being employed all winter.

**BABINE RANGE.**—Gold quartz showings on Dome mountain were staked some years ago, but until this

year little work had been done on them. An option on all the more important claims in the camp were secured this year by Mr. T. E. Jefferson, acting for a New York syndicate. Mr. Jefferson's plan of work for the season was to prospect the surface thoroughly by open-cutting, stripping, etc., Mr. A. J. Gaul was engaged as assayer and an outfit taken out to the camp; in this way all the veins were properly sampled and assayed and much information secured as to values.

There are a number of quartz veins on the mountain that are well defined and persistent; one small vein having been traced for about 4,000 feet. They are mineralized with pyrite, arseno-pyrite, chalcopyrite and some galena. The principal value is gold, apparently contained in the sulphides, and low silver values. The lead and copper contents are unimportant.

The most important showing is that known as the "Forks". This is a large outcropping of well mineralized quartz which would seem to be part of a large vein at least thirty feet wide. Average values are said to run about \$15 to \$20 a ton. This vein cropping occurs at the confluence of two creeks right in the creek-bed and is in a difficult place to prospect. Owing to the over-burden of clay, gravel, etc., and a rock capping of schist it had not been possible to trace this vein longitudinally on the surface, and it will apparently be necessary to sink on the vein to develop it. The showing, however, is a very promising one and the continuity of the small veins of the mountain gives a reasonable hope that this big vein will also be continuous.

Another large vein, about ten feet wide has also been prospected and although somewhat lower grade than the "Forks" showing, is well worth development.

It was not practicable to carry on winter work on this property, so late in the fall work was stopped, but operations will be resumed on a larger scale next spring. The property is well situated for mining, and a suitable wagon road to Telkwa can be put in which will have a length of about 20 miles.

**DRIFTWOOD CREEK.**—Development of a number of properties in the Driftwood Creek section of the Babine range was carried out during the year by the owners and others. The Highland Basin group owned by Cane and King showed up very well. This is a silver-lead-zinc property carrying good values in silver and in places promising gold values. It is a contact ore-body lying between schist and rhyolite and although irregular in its nature is likely to contain some good shoots of ore.

Other properties developed during the year were the Little Joe group, Social group, Shamrock group, Silver King group and Harvey property.

**COAL MINING.**—About 700 tons of coal was mined from the Betty mine on the Telkwa river, seven miles from the town of Telkwa. The property is under lease to Gillespie and Wilson who mine on a small scale and haul the coal to the railway in wagons or sleighs.

The Yorkshire and Canadian Trust Company, liquidators of the Copper River Coal Company, proceeded with the diamond drilling of the property of the company. This coal property is situated on the headwaters of the Zymoetz river about 40 miles from Telkwa; it was described in detail in the 1914 Annual Report of the Minister of Mines. Four holes were drilled and it is believed that the results were satisfactory in showing the continuity of the coal seams. It is expected that further drilling will be carried on next year.

**CEDAR CREEK.**—It is very encouraging to be able to record a production of about \$130,000 in placer gold from the Cariboo this year, as this is about double last year's production. This increased output is due to the activities of the new Cedar Creek camp.

Cedar Creek is a small stream flowing into Quesnel Lake on its northern shore. Sixty years ago it was worked for placer gold and a small amount taken out. Late in the fall of 1921 Platt and Lyne located good pay dirt in the gravel, and in crevices in the bedrock on a bench half a mile back from the lake and 600 feet above it. A number of leases have been found subsequently to contain workable gravel in what is presumably an old creek bed of pre-glacial times that has been left high above the present creek level.

The total production of the camp has been about \$75,000, almost all of which has been produced by rockers. This is a very creditable start for the first year and from all indications a larger production should be made next year.

**HYDRAULIC MINES.**—All the usually operated hydraulic mines in the Barkerville section were operated during the year, but as previously indicated, lack of sufficient water resulted in a small output.

The Kitchener mine at Keithley, which was equipped with an hydraulic plant last year, had a fairly satisfactory season and it is reported that a good clean-up was made.

**KEYSTONE DRILLING.**—Testing of placer gravels by drilling was carried out in a number of places during the season. Outfits were at work on the Swift river, Cottonwood river, Antler creek, Cunningham creek, Grouse creek and Lightning creek. Most of this work had for its objective the testing of the gravels to see if any suitable dredging areas could be outlined. On Grouse creek the drilling was done to locate if possible the continuation of the old channel worked on the Waverley property.

**QUARTZ MINING.**—Quartz locations on Cunningham creek were developed by Moore and Wells with encouraging results. The veins are large and in places good gold values occur. Further development work will be resumed in March of next year.

#### CENTRAL MINING DISTRICT

Subjoined is an estimate of the mineral production of Mineral Survey District No. 3 for the year 1922, this being under the supervision of the Resident Mining Engineer at Kamloops;

| Mine                                  | Gold<br>Oz. | Silver<br>Oz. | Copper<br>Lbs.                         |
|---------------------------------------|-------------|---------------|----------------------------------------|
| Iron Mask Mine,<br>Kamloops           | 12          | 2,000         | 300,000<br>(in form of<br>concentrate) |
| Liberator Mining Co.,<br>Hope         | 400         |               |                                        |
| Pioneer Mine,<br>Lillooet             | 640         |               |                                        |
| Small Placer<br>Operations            | 350         |               |                                        |
| White Elephant Mine,<br>Okanagan Lake | 433         | 170           |                                        |
|                                       | 1835        | 2,170         | 300,000                                |

With the exception of the Iron Mask Mine all the properties are shut for the season. In the case of the Iron Mask, at the present moment, about 700 tons of copper concentrate with a copper content of about 140 tons, or 280,000 lbs. is stored at the mine.

**GOLD.**—The biggest producer of gold in this district for the year is the White Elephant Mine at Ewings Siding on Okanagan Lake. 290 tons were hauled from the mine to Okanagan Lake and shipped to Trail. The average value of this ore was \$30 per ton, almost all in gold. The hauling cost, railway freight and treatment charges on the ore practically consumed all the profit. After some further development work, with the erection of a mill, this property may easily become an important producer of gold.

The Pioneer Gold Mines Ltd., operating the Pioneer Mine on Cadwallader Creek, is the next most important producer gold. Owing to breakage in the plant the property was forced to shut down in October. This year a small cyanide leaching plant was erected on this property to handle the tailings from the original stamp mill.

The Liberator Mining Co., operating the Emancipation Mine at Hope, is next on the list. Lack of development work, principally, is handicapping this property at the present time. On the property this year the construction of the small stamp mill and aerial tramway were brought to completion. The mill consists of a 7 x 9 crusher, a 5-stamp battery and one Wilfley table, the tailings from the table being put through a 3-cell flotation machine. The capacity of the whole plant is only 12 tons or so a day. More power than what is now obtained from the 50 H.P. gas engine for both mine and mill is needed before the capacity of the mill can be increased to any extent.

The Windpass Mine near Chu Chua on the North Thompson River is a gold property just recently bonded and should increase the gold production materially within a year or two.

With regard to placer operations, the Lillooet Alluvial Co., operating on the Horseshoe Bend of Bridge River, has completed all preliminary construction and is now in a position to carry on with the actual hydraulicking. This construction includes the erection of camp buildings, the building of 3 miles of flume and the installation of several thousand feet of large steel pipe. At the present moment three monitors are in position for use, derricks have been erected for handling the heavier boulders and with the warm weather next spring this should be a going concern. The success of this enterprise would mean a great deal to the district.

There have been some minor plant installations in connection with hydraulicking at Cherry Creek east of Vernon, and on the Nicola River near Bull Canyon, where in each case a flume was built, and also at one or two more points.

**SILVER.**—The silver produced in this district is of very little importance. When some of the complex silver-lead-zinc ores of the area are worked, the case will be different. At the present time almost all the silver comes from a couple of properties mentioned above as a by-product.

One silver property, the Homestake Mine on Adams Lake, is under option at the present time and has a good chance of being an important producer of silver, if not next year, at least the year after.

**LEAD AND ZINC.**—Neither of these metals has been produced in the district this year.

**COPPER.**—The small production of copper shown in the statement is all from the Iron Mask Mine near Kamloops. This property has an efficient 300-ton mill just completed and has been running one side (or half

of the plant) intermittently for a couple of months. Several oils (for flotation) have been tried out during this period and minor adjustments made. With the beginning of the new year this property should become a steady and important producer of copper concentrate. The completed mill includes a No. 4 Gates crusher, 18" x 24" rolls, two 64½" Marcy ball mills; 2 Dorr classifiers; Callow flotation rougher and cleaner rolls; two 12' x 24' Dorr thickener tanks; and two 10' x 24' x 50' conical bottom Dorr thickeners.

**NON METALLIC MINERALS.**—About 1200 tons of magnesium sulphate have been shipped during the year to the Basine Chemical Production Company from the deposits owned by the company near Ashcroft.

A small amount of sodium carbonate has been produced from Meadow Lake near Clinton. Further details will be forthcoming soon about this deposit.

#### SOUTHERN MINERAL DISTRICT

The Boundary, Slovan and Kootenay districts, which at one time almost comprised the mineral industry of the province, are still one of its most important parts. Its production at present is mainly from one large mine, the Sullivan, while a large number of smaller mines contribute a very respectable total.

**SULLIVAN.**—This mine, the outstanding zinc producer of the world, is responsible also for a respectable output of lead and silver. During the year the ore has been shipped to the concentrator at Trail, where the intimately mixed sulphides of iron, zinc and lead have been separated in the flotation plant. It is only the separation of these three sulphides by this means that has made possible the extensive use of the huge Sullivan ore-bodies. The new 1500-ton concentrator at Kimberley, close to the mine, will be completed shortly.

**INDEPENDENT MINES.**—During the year there were in operation a large number of small mines, mainly silver-lead and silver-lead-zinc, which shipped their ore or their concentrate to the smelter at Trail. The improved process both of concentrating complex ores and of smelting them have allowed the Consolidated company to offer to these independent shippers much better terms than formerly. When the 1000-ton concentrator at Trail is released for customs work on the completion of the Sullivan concentrator, it is expected that a still larger number of these small mines will be opened.

Among the independent mines operated during 1922 are the Silversmith and Bosun, Sandon; Paradise, Windermere; Standard and Van Roi, Silverton; Ottawa, Surprise, Noble Five, Meteor, Noonday and Reco, at Slovan City; Silver Hoard and Neosho at Ainsworth; Rosebery-Surprise, Rosebery; Sally, Bell and Revenge, Beavertell; Rambler-Cariboo, Rambler; Blue Bell, Riondal; Whitewater, Retallack; Alamo, Alamo; and Monarch, Field. The development of these mines is a very important matter to the wide district they cover. Among them there may be discovered at any time an ore-deposit of the first magnitude.

**ROSSLAND.**—The famous old Rossland camp has remained idle during the year. When the price of copper advances the large amount of low-grade ore remaining in these mines will become available once more, due principally to the possibility of separating the gold-bearing copper sulphides from the barren pyrrhotite by flotation.

#### THE WESTERN DISTRICT

In the Western Mineral Survey District the past year has been marked more by development than by production. The metal mines produced during 1922 only a com-

paratively small tonnage of concentrate from the Indian Chief Mine, the property of the Tidewater Copper Company Ltd., at Sidney Inlet, west coast of Vancouver Island.

The reason for this small production is that the Britannia and Marble Bay mines have been non-productive during 1922, and the Indian Chief was practically closed down owing to lack of water for power during about ten months of the year. While the small production is regrettable, yet when the new development work that has been done in the district is considered there is good reason for optimism for the future.

**BRITANNIA.**—The Britannia Mining and Smelting Company has shown to a marked degree of confidence in the future, because although their concentrating plant at Britannia Beach was totally destroyed by fire on March 19th, 1921, and the company's town was visited by a disastrous flood on October 28th, 1921, the management has during 1922 carried out extensive development work in the mines, has almost completed the construction of a new concentrating plant with a capacity to treat 2,500 tons of ore daily, the building being constructed of steel and concrete, has built new houses for employees, has replaced the railway bridges by steel bridges and in addition has settled every claim made against it for damages resulting from the flood. The development work at the mines has been principally continued at the "Victoria" mine on the northerly side of Furry Creek, about 2,000 feet south-easterly from the "Empress" mine.

It is expected that the new concentrating plant will be completed and ready to operate about the beginning of February next.

The Britannia Company have entered into a contract with the B. C. Electric Railway Company for electric current equal to about 6,000 horse-power to supplement the Britannia's present electric power plant.

The Britannia Mining Company can safely figure on 10,000,000 tons of reserve ore made up as follows:—broken ore in stopes 1,700,000 tons, reserves of "positive" and "probable" ore in place 8,300,000 tons. Of this quantity it is safe to estimate that a million tons of commercial ore have been blocked out in the new Victoria mine within the last two years.

On the Tide-water Copper Company's Indian Chief claims, the development work done during 1922 has been to explore more thoroughly the ore-body known as the "Price", which was discovered by diamond drilling in 1919-1920. The quantity of ore blocked out in this body represents a tonnage sufficient to keep the concentrating mill running steadily for at least two years.

**PROSPECTS.**—There has been some progress during 1922 on smaller mining properties in the Western Mineral Survey District. This has resulted in reopening old workings and extending the development work on such properties as the "Silver Tip", "Nancy Bell", "Saga", "Good Hope" and "Surprise" groups on Texada Island, the "You" group on Bedwell River, Clayoquot Sound, and on the "W W W" group on Franklyn River, easterly from Alberni Canal. The ore on the last two mentioned claims occurs in quartz veins in the volcanic rocks of the Vancouver series and the values carried by the ore are principally gold and silver. Small milling plants have been constructed on both the "You" and "W W W" groups.

On Texada Island the Marble Bay Mine is closed down indefinitely. Although a body of copper ore of good grade was opened below the 1700 level, being developed by diamond drilling, it was estimated by the management that owing to the low price of copper it would not

be profitable to attempt to mine the ore because of the quantity of dead work necessary to be done.

The development work on Texada Island during the past year was confined to that done by Lee, McDonald and McMillan on the "Nancy Bell" and "Silver Tip" claims; also, that done by Jack McConville and associates on the "Saga" mineral claim where a large Ross mill was constructed and operated for a few weeks.

The ore-bodies belong to the fissure vein type; the metallic content of the ore is principally gold and the gangue material is quartz. These veins occur in porphyrite country rock which is typical of the formation generally through the centre of Texada Island.

In other portions of the Western Mineral Survey District the work carried on in and around metalliferous prospects has been confined generally to the regular annual assessment work. The most important results were obtained on the "Gabbro" group of mineral claims on Jordan River about forty-two miles from Victoria where, under the superintendence of George C. Winkler, there were exposed several promising copper sulphide ore-bodies in mineralized zones of considerable extent and notable regularity.

**COAL.**—In the Western Mineral Survey District coal mining has been up to date the most important mining industry. During 1922 the production of coal from the Vancouver Island mines will have exceeded that of 1921 by about 170,000 tons. The production of coal during 1921 from Vancouver Island mines was 1,625,931 tons; the production during 1922 up to the end of November has been 1,639,262 long tons to which may be added 158,000 tons as an estimate of the production for the month of December, making a total for the year 1922 of 1,799,262 long tons.

It is gratifying to note that there has been complete harmony between the operators and the employees in the coal mining industry on Vancouver Island during the past year; agreements have been entered into for the continuation of such harmonious relations during the coming year.

The export trade to the United States will probably be considerably reduced for some time at least owing to the fact that the United States Government on the 26th of September last, put into effect the Fordney Tariff Bill which placed bituminous coal on the dutiable instead of the free list.

Under the Fordney act Australian coal is imported into the United States free of duty. Up to the present time Australian coal practically commands a monopoly of the markets in California and Oregon and is gradually replacing other coal in Seattle and Tacoma.

While the use of fuel oil on the Pacific Coast has seriously affected the market for the bituminous coal of Vancouver Island yet it is anticipated that the introduction of Australian coal will in future prove a very much more serious handicap against Vancouver Island coal than has the competition of fuel oil. About the only remedy against the introduction of Australian coal into the Pacific Coast States would be the removal by Canada of the import duty on bituminous coal into the Dominion, which action would be followed by the automatic removal of the import duty on Canadian bituminous coal into the United States.

#### NORTHWESTERN DISTRICT

The northern part of the Pacific coast of British Columbia owes its present prominence mainly to two mines,—the huge copper deposits of Hidden Creek that supply the Granby Consolidated smelter at Anyox,

and the Premier gold-silver mine at the head of Portland Canal. There are numerous properties under development, some of which promise to make mines; but the record of mineral production for 1922 rests upon these two.

**PREMIER.**—The marvellously rich ore-shoots of the Premier mine have now yielded a return to shareholders of about three million dollars. The ore is so phenomenally rich that it has required comparatively little mining to take out the ore that has given this net profit. The mine is privately owned, and no statement as to ore reserves has been made public. Already the rich ore-shoots have lasted longer than most rich bonanzas.

There has been feverish activity in an effort to find a second Premier in the area north of the town of Stewart, but so far without success. On the Big Missouri property a considerable amount of development work has been done, but its future is not yet assured. There are a number of very promising prospects that are undergoing systematic development.

**ANYOX.**—To the Anyox smelter is due the credit for the Province's 1922 production of copper. It is one of the few plants on the continent, or in the world, that conducted smelting operations continuously throughout the year, in the face of discouraging conditions. This was done by virtue of some outstanding metallurgical work, based on successful scientific research. The Granby company is now in a very sound position by reason of the initiation and resource of its engineers.

**ENGINEER MINE.**—The well-known Engineer Mine, now free for the litigation that has hampered its development until recently, was thoroughly examined during the summer by representatives of eastern Canadian investors. The result of this examination has been, presumably, unfavourable, for no further move has been made to develop the property. It is, apparently, like the majority of bonanza showings, and thereby unlike the near-by Premier Mine, in that its early promise has not been fulfilled.

Everything considered, British Columbia's mineral industry is in a very healthy state. There are a number of outstanding mines of world-wide fame; there are numerous smaller mines, scattered over a wide area; there are an unusually large number of prospects under development, among them a considerable proportion of unusual promise; and prospectors are bringing to light new deposits that will ensure an ever-increasing mineral production for the province.

In the legislature of South Australia a government bill has been introduced to abolish compulsory arbitration. The Board of Industry and the Industrial Boards are to be retained as a means of adjusting labour disputes.

It is proposed to re-examine the famous Thames placer field of New Zealand, which yielded \$35,000,000 from a small area. It is stated that exploration with modern methods and with the thoroughness now possible is certain to be remunerative.

The total production of Gold on the Rand, South Africa, since it was opened in 1884 has been approximately £700,000,000, or 163,250,000 ounces. The Crown Mines, the largest individual company, has contributed 13,000,000 ounces to this total. A total of £154,000,000 has been paid in dividends throughout the field.

# The Mineral Industry In Manitoba, 1922

By J. S. DELURY \*

During the past year there has been the customary activity in the production of non-metallic mineral products, part of which are gypsum, stone, cement, clay products, lime and sand lime bricks. Production tables are not yet available for the year but it is expected that the normal increase that has been shown during the years following the war will be recorded again for these materials. On the other hand, there has been no production of the metals. The production of these in Manitoba was confined to a four year period, 1917-1920, during which time the following were produced:

|              |             |
|--------------|-------------|
| Copper ..... | \$2,039,942 |
| Gold .....   | 179,844     |
| Silver ..... | 57,667      |

As production totals, these figures are small as compared with most of the other Provinces, but they will serve to indicate that Manitoba has some possibilities as a metal producer. While there has been no production, there have been some activities in most of the metalliferous areas of the Province during 1922, namely in the Flinflon, Copper Lake, Elbow Lake, Rice Lake and Bird River districts.

It will be recalled that nearly 17,000,000 tons of copper ore carrying low values in gold and silver were blocked out by diamond-drilling on the Flinflon claims during the past few years. Exploration work was continued on the same deposit until the fall of the past year, chiefly in the way of further drilling. It is reported that a body of high-silica fluxing rock of sufficient size to meet smelting requirements has been found by representatives of the Flinflon interests on Tartan Lake. Dr. Alcock of the Geological Survey, Department of Mines, had a party in the Flinflon area during the summer, engaged in detailed geological work.

Similar operations to those on the Flinflon deposit were conducted on two properties on Copper Lake by parties representing Cobalt interests. Diamond-drilling was done on one of the large deposits of sulphides found in that area as well as on a large low-grade quartz vein. Several mining interests had representatives in the Elbow Lake area during the summer, doing work on the Murray claims as well as on several small veins that have spectacular showings of free gold. Some active prospecting has been going on in many parts of Northern Manitoba, particularly in the vicinity of Herb Lake. Some new finds of gold are recorded from this area. The Apex group of claims on Herb Lake was carefully sampled during the summer for some Cobalt interests and as a result, some steps towards active development work on these claims are expected. The Rex Mine on the same lake was examined for several different concerns. There is unanimity of opinion that the Rex will make a profitable small mine, and only the difficulty in arranging terms is deterring its operation. No work was done on the Bingo group of claims until November when sinking operations were resumed. The shaft is now down to

about 200 feet. Money was raised in London for its development, new machinery has been ordered and an active development program has been arranged. The principal showing on this group of claims is on the Bingo where a number of small parallel veins occur fairly close to each other. The shaft was sunk on one of the most promising of these, the others being within 50 or 100 feet from the shaft, across the strike. Values in a 6 to 10-inch quartz vein run about \$150 fairly consistently in the shaft and on the surface. No attempt has yet been made to cross-cut to the other veins from the shaft, but it is planned to do this when the shaft is deeper. There are some other promising properties in the Herb Lake district, which will probably have to wait for results from the Rex and Bingo developments before it will be possible to finance them.

Some very rich silver samples, said to have come from a rather inaccessible part of Northern Manitoba, have been shown in Winnipeg. A sample seen by the writer showed abundant finely disseminated silver in calcite. Its unlikeness to any of the Ontario silver ores makes the story of its finding and source all the more credible. It is understood that some parties have taken to the field this winter in search of the silver deposits, or to be on hand for the spring search and locating.

One party prospected on Knee and Oxford lakes during the summer and brought back some samples that indicate the presence of a considerable body of low-grade copper ore on the south shore of the latter lake.

The Selkirk Mining Company, financed by a strong group of New York capitalists, has been doing steady underground development work on the Luleo group of claims, which are located in the Hole River area of the Rice Lake district. The work is being done on a large gold-quartz vein which occupies a shear zone in granite. Over 800 feet of work has been done in sinking, drifting and cross-cutting. Values so far obtained are sufficiently good to warrant further development, and this is promised. There have been some small attempts made at the milling of small high-grade deposits of gold-quartz in other parts of the Rice Lake district during the summer, but there seems to be a tendency on the part of those interested in this district to wait for the results of the work being done on the Luleo vein. This deposit is one of the most promising in the district and its operation is guaranteed should the results from development continue to be encouraging. Dr. Wright of the Geological Survey, Ottawa, spent the summer with a party in the Rice Lake district.

Considerable interest has been taken during the past few years in the Maskwa River and Bird River areas where copper-nickel deposits, similar in some respects to those at Sudbury, were found at several points. Little work beyond that required as assessment was done during the year. However, some serious development work is planned for one of the deposits. A diamond-drilling outfit is now in the area ready to commence operations on the Devlin-Martin claims. The extent of drilling will depend on developments as the work progresses, no definite pro-

\* Dept. of Geology and Mineralogy, Univ. of Manitoba.

gram of work having been outlined beyond the first thousand feet or so.

Nothing has happened during the year of particular interest in connection with the non-metallic mineral industry in the Province. Perhaps the most interesting feature was the development of a granite quarry on the Greater Winnipeg Water District Railway, about seventy miles from Winnipeg. Large blocks of very fresh granite of a great variety of colors and grains have been taken out and a growing market is

being found for the products, locally and in many parts of eastern Canada and to some extent in the United States. Some search has been made for oil in the vicinity of Stoney Mountain and Stonewall. One well was drilled and results from it do not indicate any particular merit in the type of divining rod which was used. It is understood that some work has been done in the Turtle Mountain area in an effort to find workable bodies of coal among the Tertiary lignites which are known to exist there.

## Mining Investments In 1922

By ALEXANDER GRAY\*

That is the subject assigned by the Editor. His intentions are more complimentary than humane, since it calls for a complex role, for which the parquet may have bouquets—and the galleries something worse than cat-calls.

"Investments" in mining, it may as well be admitted, lose much of their attractiveness when the strictly investment stage is reached. Gradations from Speculative Investments, to Gambling on the chance of a prospect developing into a mine, are incapable of definition by any but the academic. All the Crystal Gazers on earth, all the aggregations of Mahatmas, all the Occult Sciences visioned by Blavatsky, Lodge and Doyle, cannot determine the etherical partition separating risk from certainty. Even Schawb, greatest of Steel Masters, and a successful speculative investor, avowed that when a stock arrived at the dividend stage, it lost much of its attractiveness. At the Rand, most consistent of gold fields, when earning capacity became stabilized, speculative funds became unresponsive. Therein are the dangers of dogma and the putrescence of speculation that can be overdone where ordinary foresight would obviate a great deal of the mischief wrought by those who magnify or misrepresent. Skepticism to extreme never yet brought reward, any more than will over-speculation.

Emphatically it may be stated that Canadian mineral resources have beckoned to capital. They are not to remain comparatively inactive and useless assets. Of unquestioned amplitude and diversity, they are providing more credit than has been realized by those who consider mining to be a menace to small savings and large bank balances.

Ontario having produced nearly a quarter of a billion dollars in Nickel and Copper; about \$210,000,000 in Silver and approximately \$108,000,000 in Gold; British Columbia having added about three quarters of a billion to the wealth of nations from its mines, placers and non-metallic minerals, the basis of credit is not lacking by any manner of means.

Cobalt dividends approaching \$100,000,000—a quarter of that from the Nipissing, over \$11,000,000 from Coniagas, nine and a quarter millions from Kerr Lake, \$7,500,000 from La Rose, over \$6,000,000 from Crown Reserve, and five and a half millions from the Mining Corporation of Canada, irrespective of what the companies incorporated in it paid prior to their being merged, another five and a half million from McKinley-Darragh,—lend fervor to the hope that "another Cobalt" will be found before the present Cobalt becomes passive.

It was those companies—all classified at one time as wild cats or rank speculations,—that caused a furore and wrought havoc with public confidence. "To be something we are not: to have something we have not," wrote Sir Richard Temple, "is the root of all evil." The cluster of Cobalt's gems undoubtedly inspired more speculation than

was justifiable, but whatever of speculation characterized central Cobalt has been speculatively profitable in South Lorrain and elsewhere, although the Montreal River has yet to dilute early fictions with more than a dash of fact.

### *Re-investment from Cobalt*

Precedence is given to Cobalt and its influences—notwithstanding the general antipathy once manifested toward the Wonder Silver Camp—because the mining investments of 1922 in greater part owe their origin to Cobalt and its millionaires. Wealth won from the silvers has been distributed throughout the Northland, the Northwest and the Pacific territory. With \$24,720,000 turned over to its shareholders, and four more ready, Nipissing has tried to find some new deposit conforming to its standard. As a profit-sharer it would like to maintain its front rank position; so it made a speculative investment at Claw Lake, drilled it, and also a portion of Kirkland Lake—but did not find what it wanted. Coniagas devoted itself to Newray, Matachewan and Larder Lake, eventually reverting to southeastern Coleman, where there is enough silver to make it interesting. Mining Corporation of Canada, always alert, extended its lines at the Flin Flon, concentrated on its increasingly important areas in South Lorrain, and was open for engagements throughout the year. Keer Lake interests entertained the Goldale properties at Porcupine, where the prospects promise a return upon a speculative investment. Buffalo money and its influence made a mine out of the Teck Hughes, at Kirkland Lake. Crown Reserve funds may create a credit mark for Larder Lake, a result that would be deserved, for this company has been vigilant and left nothing undone toward acquiring a healthy place for a reproductive speculative investment. Beaver money made Kirkland Gold a producer. Temiskaming as well as McIntyre, put Blue Diamond Coal where it sees a profit. Although Trethewey is affiliated with its neighbor at Cobalt, its life is prolonged in the Castle-Trethewey at Miller Lake.

Clearly, therefore, the speculative investments of 1922 were largely of Cobalt's making. The greater portion of Hollinger Consolidated capital came from La Rose and Princess. At the end of the year Hollinger—the speculation of 1909—had paid almost \$20,000,000 in dividends, and there was more than \$7,000,000 in surplus, unless the purchase of the Schumacher encroached upon that. Denison money, made to some extent at the Buffalo Mine, gathered more in the Dome and Dome Extension. McIntyre during the year took an option on the Schumacher Veteran Claim adjoining the Dome. Had Nipissing taken the Rochester Veteran Claim, the roster of Cobalt companies or individuals interested in gold properties would have been reinforced. For the same reason, it would have strengthened Elbow Lake had individual Hollinger Directors and officials continued their explorations there.

\* Consulting Engineer, Montreal.

*The Gold Developments*

The logic of outputting events, first at Cobalt, then at Porcupine and subsequently at Kirkland Lake, sustained fully those who profited most therefrom in their optimistic and prompted speculative investment of domestic funds. Reinvestments and the results, the knowledge that Canada as a whole has mineral wealth comparable with, if not exceeding that of other mining countries, have made 1922 memorable in spite of adversity in other directions. American mining capital and business interests employed their surplus capital in Canada. It is in the Bidgood, the Harvey, the Martin and other of the newer ventures. Without being invidious, the paramount transaction of the year was the transfer of nearly three miles of potential producing country at Kirkland Lake to Continental Mines, which also acquired the Colonial and Silver Cliff properties at Cobalt. The moving spirits in that undertaking had retreated from anything of the sort in Northern Ontario, and some of them had sent innumerable propositions to the scrap heap. They were trained to "take no chances," had to have a double cinch on what money was sought from their principles or themselves. Speculative investments had to be amended to suit conditions, before they relaxed their grip upon option or purchase money. They remained aloof so long from Northern Ontario, they were thought to be petrescent, until it became obvious even to themselves that they were at the wrong end of the telescope. Hence the acquisition by them of the largest block of ground in close proximity to the producing section of Kirkland Lake, and a campaign that has impressed other groups of capitalists.

Had Continental Mines been organized on the impulse and relied upon "washing" machines to procure capital, the departure would have attracted less attention. There were purchase commitments, prospecting costs, and a development program at Kirkland Lake, and the taking over of the Colonial and Silver Cliff at Cobalt was a double capital charge, involving a three-compartment shaft to a depth of 800 feet, where the O'Brien-Colonial contact vein is counted on to make an investment out of the speculation. Meanwhile a projection at Kirkland Lake, substantiated by the discovery of an ore-body, makes the distinctive speculation of 1922 in that field, prophetic for 1923. Moreover, closely affiliated principals not only are pleased with their Continental prospects but they have become identified with one of the Rouyn Township, Quebec, areas, where the showings compare favorably with those of other fields. London has a small part in this Quebec development. Apart from that, it may be interpolated, London confined its attentions to Northern Tisdale and Matachewan. The latter now may make a demonstration, as hydro-electric power will be available. Somehow, though, New York is quiescent as to its Matachewan holdings, and \$360,000 in estimated ore reserves. London, too, yielded the "V. N. T." right of way to Toronto share dispensaries.

Pittsburg capitalists have earnestly proceeded with the development of their Nighthawk Lake areas. They have acted on the belief that they have a mine entitled to a mill, tonnage and widths being sufficient in their judgment. While the capital is the largest of any gold mining company in the district, excepting Hollinger, the area is extensive, and the chief owners are most optimistic regarding it. Their own money has been forthcoming; they paid off certain of the vendors, and that is evidence of their confidence. A recent offering of further shares had for its object the provision of milling equipment and power. As it antedates Porcupine, Nighthawk Lake is due for the run it is having. In that the Pittsburg people privately subscribed a considerable amount before seeking public support, they are entitled to special commendation.

Deloro Township and areas around the Dome came in

for a share of notice. The Paymaster, formerly the Standard, under Boston auspices, is said to have a porphyry contact situation with some spectacular ore. There was a porphyry contact years ago, that was found and lost. The latest is vouched for by disinterested eye-witnesses. The McKay and Imperial are alleged to be under option. The North American Gold Corporation holding, originally the Ankerite, has New York Headquarters and a Delaware charter, and expects to start operations. Because of local conditions and Dome developments, the Ankerite has possibilities, apart from the tonnage developed and indicated, and aside from the prejudice against iron carbonates, which really seem to form but a small portion of the mining area.

While the adventitious regard Deloro as likely to be brought along when capital and cheaper power are more plentiful, the patrons of Shining Tree are as persistent and impertrurbable as those of Lightning River and other sections of N. E. Ontario. Mr. Cyril Knight lent the weight of his professional opinion to some of Lightning River. Dr. W. Harvey Weed was more emphatic regarding Shining Tree, where the Tonopah Company has made the greatest effort yet to make a mine. Beyond that, the district has had more "froth flotation" than fructification. It has survived all nursery years and is thought to be on the eve of more conclusive determinations.

*Progress in British Columbia*

Money and good management are making British Columbia a centre of activity from boundary to boundary. Most of the new money is coming from outside Canada. The Government and Minister Sloan are co-operating by assisting with better transportation facilities. The Premier Mine has been an inspiration to the whole country.

There are other properties obtaining money for development. Because of the values being obtained at the Indian Group, Portland Canal, the hope is that much larger operating facilities will be needed before the new year is far advanced.

An economic error of judgment obsessing many is the assumption that early indiscretions cannot be outlived. We must not be unmindful of the great progress that has been made in numerous instances in spite of initial financial operations that seemed enough to snow under the respective properties forever.

If evidence were lacking of what the mineral industries of Canada are capable, the preliminary figures giving the value of the output of the Province of British Columbia supply the proof. The year of depression in other lines has been a year of substantial progress in the province's mining industry. In 1922 the mineral output of British Columbia was estimated at \$32,167,463, a most satisfactory gain of \$4,100,822. The feature of the total is the continued progress in precious and base metal production, that of gold amounting to a net gain for the year of \$1,079,462; in other words, the gold output now has receded to \$4,116,815. Silver gained \$2,422,953, bringing the aggregate for the Province to \$4,034,154. Notwithstanding Granby activities, copper value was lower, and coal, singularly enough, showed an increase of \$377,095.

Analyzing those figures, and having in mind that the Premier company was credited with shipping 49,205 ounces gold and 1,572,951 ounces silver in 1921, it need hardly be emphasized what influence the production of that remarkable property had upon the total of the Province. It is semi-officially intimated that the Premier gold production in 1922 was 137,000 ounces gold and 4,500,000 ounces silver. No comment is called for. The Blue Ribbons are there for the management, the mine and men who had the nerve to develop and equip this Leah of recent years.

Meanwhile the interests have been seeking investments in the immediate vicinity; most of the ground is acquired. That is why influential owners are freer to talk. Montreal and Toronto people of financial and mining experience have been pursuing a constructive policy at the Indian Mine, which is approximately 1500 feet removed from the northern line of the Premier. While there have been numerous new ventures during the year, the Indian at-

tracted most attention because of its sponsorship and the reports emanating from Mr. Turner in charge. Three adit levels have been opened up, and raises and winzes are being carried on. Instead of a problem, of which Portland Canal District has presented plenty to every company there, the indications are that the Indian has greater possibilities than pioneers could or would concede to it.

## Recent Developments in Metallurgy in Canada

By G. J. MACKAY\*

The practice of technical journals in viewing at this time of the year the status of, and developments in, the several industries has become well established. Many of us welcome the January issues in order to find this retrospective view set forth in brief and readable form. It is an arm-chair pleasure to wander lazily with the contributor over some industrial field and dreamily to congratulate ourselves on how much more we know about certain phases touched upon than he apparently does.

A brief backward glance over some of our Canadian metallurgical enterprises during, say, the last two or three years may not be without interest. Progress has been made in nearly every quarter, much of it unrecorded except indirectly in the financial success of our mining enterprises.

### *Copper*

The Granby company was one of the few copper producers in North America that continued operations throughout the depression of 1921-1922. In the summer of 1920, under the new management at Anyox, drastic changes in the smelting practice were introduced; the reduction in the amount of coke and barren flux used did its part toward keeping costs down. The three cuts in wages agreed to by the employees, and the improvements made in the power supply, were further important factors.

At Trail the plans of the Consolidated company to erect a concentrator to treat Rossland ores and so renew the youth of these mines has been held in abeyance. Until that programme has been carried out and the copper market has further improved, the new rod mill will not come into its own as a source of strength in Canadian mills.

### *Zinc and Lead*

The sums spent on a competent research staff and large experimental plants at Trail have been more than justified by the success attained with the Sullivan ore. The treatment of this finely disseminated mixture of sulphides of zinc, lead, copper, and iron has been mastered. Selective flotation, with a little assistance from tabling of the middles, is giving satisfactory concentrates for the electrolytic zinc plant and the lead blast furnaces. The refinements introduced in the treatments and the additional equipment installed in the zinc and lead plants have made possible a reduction in costs of power and a very complete recovery of the lead, with a great reduction in the former loss of zinc. These improvements have enabled the Company to share the benefits with the mine operators of British Columbia, as is shown by the amended schedule of treatment rates now in force.

The surface equipment of the Kingdon mine at Galetta consists of a mill and a Newman ore-hearth smelting the

high grade galena concentrate produced. This is an example of a small mine with a complete and model plant that has continued to operate profitably through the recent depression in the metal markets. A new blast furnace has just been added to the equipment, which is now complete in every detail.

### *Gold*

The mill men at Porcupine have not rested on their laurels, but have adopted new ideas from the experience of others or, more often, used their own ideas to meet the changing nature of their ores with depth or to avail themselves of new economies in treatment.

At the Hollinger, the use of a ball mill in parallel with the stamps demonstrated that the time for a change had come. A carefully conducted series of tests of two ball mills of different types and a rod mill has led to the decision to replace the stamps by rod mills. Oliver filters have recently been installed to reduce the loss of dissolved gold and cyanide in the residue as discharged from the continuous decantation plant. Here, as at most of the mills in Northern Ontario, a Crowe de-aeration unit is in use.

In some gold camps, fashion rules in mill practice and equipment. This is not the case at the Porcupine mills and perhaps least of all at the Dome. The metallurgist in charge there has his own little pet experimental plant, which is seldom idle. The efficient work done is more than creditable in a mill that has been hashed about as the Dome mill has been. Eight years ago, a sand leaching plant was added to give greater treatment without added crushing. Recently all-sliming has been again adopted, the ore of to-day requiring fine crushing. Amalgamation is adhered to and even blanket strakes, or their equivalent, are used to retain liberated gold that has failed to amalgamate. High extraction and low costs govern in the Dome mill regardless of appearances. Another evidence of untrammelled judgment is the change in the treatment of the gold precepsitate; the litharge smelt-cupellation has been replaced by the "old fashioned" acid-wash—calcining—melting process, with very satisfactory results.

About three years ago at the McIntyre mine, graphitic schist was met with in parts of the ore-bodies and caused some apprehension. Its presence in gold ore is always accompanied by premature precipitation in cyanide treatment. Undaunted by the fact that this difficulty had never been satisfactorily overcome, the metallurgist in charge attacked it. By a lengthy series of laboratory experiments followed by large scale tests, it was found that grinding in water containing a little light mineral oil, dewatering, and cyaniding was the remedy. The oil coats the freshly broken particles and prevents the adsorption of the reducing agent that causes the precipitation. An addition to the mill was erected last summer to house the

\* Professor of Metallurgy, Queen's University, Kingston, Ont.

apparatus required by the new flow sheet and to increase the total capacity. However, underground development has proved that the graphitic schist is local, the parts of the ore bodies affected being of no great extent.

In the Kirkland Lake camp, five new and more or less model mills are at work. The rumble of the stamps is missed; intermediate crushing is done in ball mills. All slime treatment is carried out by means of Dorr equipment. The thickness of the pulp in the agitators and the length of agitation are striking features in some of the mills. For tonnage, the former is necessary to permit of the latter. The long agitation is required owing, possibly, to the presence of gold tellurides.

**Stamping up.** (1) It seems that the stamps have had their day. Rolls and ball or rod mills have conquered them even on rather hard and tough ores. (2) The efficiency of tube mills makes fine grinding profitable on most gold ores. (3) In Northern Ontario amalgamation before cyaniding is not favoured. Is this good policy or not? At any rate, to install plates would now mean to train a new generation of amalgamators.

#### *Silver*

Cobalt is well known for the excellence of its concentrating practice and for the remarkable work that has been done in devising means for the successful cyaniding of its very refractory ores. Of more general interest is the very fine grinding that is being done in its cyanide mills of late years. The economic limit of fineness is not reached with a 200-mesh product, and the sand from this is re-ground. Perhaps such fine grinding is justified in the case of few other ores except the tellurides of West Australia. At Cobalt the use of the bowl classifier and of the tube mill with steel balls replacing pebbles, has made this an economic success. An exhaustive series of tests of an apparatus that marks a radical departure in fine grinding practice is nearing completion and will yield something of interest to gold and silver mill operators.

The mill at the Premier silver-gold mine in northern British Columbia has been in operation long enough (since July, 1921) to prove its efficiency. Flotation and cyaniding are employed on an ore containing many refractory silver minerals. The concentrate is carried to tide-water by an aerial tramway over eleven miles long and is shipped to Tacoma.

#### *Nickel-Copper*

During the greater part of the last two years the smelters of two of the nickel companies have been closed and the third has been working at low capacity. The companies have been devoting their energies to devising means of producing pure nickel and nickel alloys. They are now turning these out in quantity and are seeking new markets for them to replace the armament uses of nickel. The Mond Nickel Company is making pure nickel in its plant at Clearfield, Pennsylvania. The British-America Nickel Corporation is producing pure nickel at its Deschenes, Que., refinery by means of a second electrolysis. The purified metal is highly malleable and welds perfectly to steel. The International Nickel Company is making monel metal and other nickel alloys in its plant at Huntington, West Virginia. All its refining will, in future, be carried out at Port Colborne.

The Mond company is doubling the size of its flotation and Dwight-Lloyd plants. This will give a lower silica and higher iron blast furnace feed, which will be self-fluxing.

The British America Corporation has run its smelter at Nickelton on rather unusual lines. A heavy duty was put

upon the converters by using siliceous ore in them instead of barren quartz; the great quantity of slag resulting was returned to the blast furnace where it acted as a very satisfactory flux; this entailed the handling of a great deal of slag but gave a large matte output from a single blast furnace and its converter. At Deschenes the Hybinette electrolytic refining process, considerably modified, has been used. This gives casting copper and high-grade nickel and leaves the precious and rare metals in a concentrated and easily treated product. It is said that the company has secured contracts for a large output of nickel and will recommence operations shortly.

The possibility of the differential flotation of copper and nickel sulphides from finely ground Sudbury ore is attractive and has been receiving the attention of investigators for the last few years. From the nature of the occurrence of the nickel sulphide, it is a difficult problem. The possibility of roasting and wet treatment of these heavy sulphide ores seems still more remote, especially as the nickel sulphide is averse to treatment that will make the nickel soluble on a commercial basis. When the great nickel corporations have solved their present problems of new works, they may turn their attention more definitely in the direction of new methods of treating their ores.

The Deloro smelter continued to operate its silver and arsenic department during the recent lean months. The Cobalt plant was re-opened in June after a year's shut-down. Additions for the manufacture of insecticides and of cobalt salts have recently been brought to the producing stage. The whole plant is now working at capacity and turning out a number of finished products of cobalt, nickel, and arsenic.

#### *Iron and Steel*

The question of a domestic iron ore supply is only secondary in Canada at present to the supply of fuel for the central Provinces. The Ontario government is seriously considering the pros and cons of granting assistance to iron ore producers and the British Columbia government is considering the possibilities of a Coast steel plant.

The practicability of the commercial beneficiation of our low-grade magnetic ore, which is known to be available in large quantity, and the smelting of the resulting produce, are two pressing questions in Canada. The concentrating-sintering plant at Babbitt, Minnesota, is a centre of interest for Canadian iron and steel men. The question of just how the sintered concentrate will act in the blast furnace is also of the greatest interest.

The problem of the application of the electric furnace to the smelting of iron ore or concentrate in this country is likely to be left unsolved for many years to come. When we consider the dearth of fuel and the abundance of water power in our industrial Provinces, we are almost envious of the success attained with the electric shaft furnace in Norway and Sweden. However, a comparison of conditions is not encouraging. There, a higher grade of pig-iron than we can hope for is produced, power is much cheaper than with us, and a saving in charcoal is a greater economy than a saving in coke.

Canadian metallurgists have had their full share of difficult problems. These have been met by alert, resourceful, earnest men. The patient labours of trained investigators have brought uniform success. The achievements of these men in the past give us confidence for the future, with its still more refractory and low-grade ores and its ever-changing market conditions and industrial demands.

# Mining Methods in Canada

By S. N. GRAHAM\*

From year to year we have become accustomed to reading, in the annual review numbers of the technical journals, of the great strides and improvements made in metallurgical methods and processes. The metallurgist is impelled to make these improvements by the ever-increasing pressure of competition, by changing economic conditions, and by the present necessity of treating ores that were at one time considered too rebellious to handle. His researches have been aided by the fact that in the laboratory he can make a large number of experiments in a comparatively short time. Considered from this viewpoint, the miner works under a great handicap. He cannot make experiments in the laboratory, but must have them made in the mine. Here he labours under the difficulty of having daily to produce the required quantity of ore, and no experiment may be allowed to interfere with this. Furthermore, if he has the temerity to try an experiment with the object of improving his mining methods, he must carry on his experiment with such large quantities and on such a large scale that the result of a single test may not be known for months or even years. It is not surprising, therefore, that along with a review of metallurgical improvements there is not always a review of mining improvements. Just as the experimenter is handicapped, so also would be the reviewer.

## *Shrinkage Stopes Almost Universal*

From what has been said it must not be inferred that mining methods are not being improved. The exact opposite is the case; but the curve of progress does not show any steep or sudden peaks. One has only to read the description of mining methods as given in such classical books on mining as those of Le Neve Foster and Ihlsing, and then look at the chart of modern mining methods, prepared by the American Institute of Mining and Metallurgical Engineers, to see that really tremendous advances have been made. The time-honoured open stilled stope and the square-set stope, with their ever-increasing timber cost, have practically disappeared. The hard-worked mine superintendent has evolved methods that permit the safe and economical mining of the most difficult deposits and that overcame the disadvantages of these two old systems.

It is appropriate to point out here that nearly all Canadian ore deposits develop into what may be called "hard rock" mines. While this condition makes the ore harder to break, it is, in part at least, compensated for by the fact that the walls are unusually strong. This, coupled with moderately wide, or wide, ore-bodies of steep dip, has made the "shrinkage" method a favorite in our mines. So common is this method that it may be said to be typical of Canadian mining practice. While it is a type, it is not a "form" method, because nearly every mine shows minor variations. These are due largely to differences in the dimensions of ore-bodies or ore-shoots, and are characteristically shown in the way access is obtained to the stope for men and material. One very striking variation is seen in the wide ore-body of the Creighton mine where the length of the stope is transverse to the strike of the deposit.

## *Sub-Level Stopping*

While shrinkage stopping has been mentioned as a characteristic method, it is not applicable to all deposits; but when the dip is not too flat it seems the most suitable. For

flat dips, when gravity will not move the ore to the drifts, the drag-line scraper has been adapted to underground use, as in the Sullivan mine. Where the ore was required to be used immediately, the sub-level stoping method was successfully used in the Magpie mine. The whole-sale bench mining now being tried out at the Hollinger mine is a most interesting experiment. It shows that no efforts are being spared to improve methods in Canadian mines.

Both drift pillars and stulls are used for protecting the drifts, the particular method adopted depending on the grade of the ore. When the grade of ore in the pillars is sufficiently high to ensure a profit after timbering, then stulls are used. There is thus an economic limit that has to be worked out for each individual stope, as has been done at the Hollinger mine, where both methods are used. Of course the pillar ore may be recovered ultimately; but in some cases the expediency of recovering it may be considered with a question mark after it. However, the pillars can be mined, as witness the very successful pillar-drawing at the Creighton mine.

Thus continued practice with the shrinkage method has enabled the mine superintendent to overcome many of its disadvantages. Sad experience has proved that the ore drawing requires close supervision; but, given this, there results less trouble and fewer accidents from ore hanging up over the chutes or box-holes. Some disappointing results show also that close supervision must be given to ore breaking in the stopes. If this is not done a very large factor for waste dilution must be used. On the other hand, if too much caution is used some stopes will require sweeping down and the ore left in the walls will have to be mined. Unless the ore is high-grade this does not pay. Low grade ore left in the walls is absolutely lost.

## *Careful Sampling*

Partly as a result of this last feature, a visitor is impressed by the extremely close and careful stope sampling seen in most of the mines. Nearly every bench is channel sampled, and drill-hole samples are taken from the walls at regular intervals.

This close supervision of underground work may be said to be the greatest modern improvement in mining. Such supervision, however, loses much of its value unless careful records are kept so that the inferences made from comparing records may be certain, and not mere guesses. The foreman, or shift-boss, must therefore be a man who, along with his other practical qualifications, is capable of keeping proper records and appreciating their value. Whether due to a demand for this type of man or because other engineering positions are hard to obtain, the fact remains that now one finds many young technically trained engineers working as foremen and shift-bosses. If these men have passed through what may be called a working apprenticeship as miners, as most of them have, then they should make most efficient foremen. Besides being of a high type of intelligence, their engineering training develops a sense of justness and fair dealing that is the most essential requirement for the successful treatment of labour. With such material to select from, men with both technical training and practical experience in handling mining operations and labour, Canadian mining companies have a splendid supply of capable and efficient superintendents and managers.

\* Professor of Mining, Queen's University, Kingston, Ont.

### *Geologists Direct Exploration*

An official now found at nearly every mine is the mine geologist. It is a commonplace to say that the more simple, easily found, and easily worked ore deposits are exhausted. The deposits now worked are more complex both in physical and geological features. It certainly points to improved conditions and to enlightenment and broad mindedness on the part of mine managers, that they appreciate what a mine geologist is capable of doing. In many cases it is he who now prepares, for approval by the manager, plans for exploratory work. Just how much he may gain or save for his employers is often incapable of direct proof. However, he is often enough able to prove direct saving of money more than sufficient to justify his existence.

One of the most obvious results of the mine geologist's labours is the construction of mine models. Whereas some years ago these were more or less a curiosity, they are now found at nearly every mine. The glass plate type of model seems to be the favorite. These are usually made up of horizontal plates on which the principal workings and geological details are marked. However, vertical sheet

models are also used where this type is better adapted to show the geological structure, as at the McIntyre mine. Such models are of the utmost value in aiding those directing the underground work to visualize the ore body and the geological conditions surrounding it. This must undoubtedly lead to more intelligent prospecting and exploratory work.

But the mine geologist's work is not confined to directing underground exploration, for his aid is being more sought in opening raw prospects and in prospecting favourable territory. An example of this is seen in some work done east of Kirkland Lake during the past summer. Here surface trenching was carried on under the direction of a geologist. The amount of trenching done in following up promising leads would indicate the belief that, for preliminary work, a dollar spent on the surface will give more information about a vein than a dollar spent in sinking a shaft.

We have every reason to look with pride upon the present status of Canadian metal mining. So long as the personnel of operating mines is kept up to the high standard now attained, we need have no fear for the future.

## Canadian Ceramic Industries in 1922

By N. B. DAVIS\*

The Ceramic Industries include all those based on non-metallic minerals treated by fire in the process of manufacturing into useful products. These include heavy clay wares such as brick, tile, sewer pipe; pottery, enamel ware, cement, lime, gypsum, magnesite and abrasives.

The general revival of building operations, during 1922, particularly in the larger centres of the East, had a very favourable influence, and many plants worked to capacity.

### *Heavy Clay Products*

Brick, hollow tile, sewer pipe and drain tile plants were rushed with orders, and several are still pushing out ware to meet the demand at a time when, in other years, business has slowed down. No new plants were put in operation, but a start was made by the Interlocking Tile Company to re-model the Shaw Brick Plant at Avondale, Nova Scotia to turn out Dennison Hollow Block. At Medicine Hat, Alberta, sewer pipe and stone ware pottery business showed an increase, and to take care of this some 170 car-loads of stone ware clays were shipped from East End, Saskatchewan.

### *Pottery*

The manufacture of pottery in Canada is limited to a few plants such as the Canadian Porcelain Company, Hamilton, and the General Electric Company at Peterborough, turning out electrical porcelain; the Trenton Potteries and Dominion Potteries at St. Johns, Quebec, manufacturing porcelain plumbing supplies; the Campbell Pottery at Hamilton and the Medalta Pottery at Medicine Hat, turning out stone ware articles. At Kingston, the Frontenac Floor and Wall Tile Company continued to produce vitrified floor tile, and started grinding feldspar for their own requirements. The first unit of a new electric porcelain plant was erected at Niagara Falls by a subsidiary of the Ohio Brass Company, Barberton, Ohio.

### *Cement, Lime and Gypsum*

Plants producing these structural materials all enjoyed the increased business derived from new construction. No new plants were erected or new deposits opened up.

### *Magnesite*

The Canadian Magnesite production has shown a slight improvement and an increasing market is opening up for this material, coincident with the increased use of stucco.

### *Raw Materials*

The China clay mine at St. Remi, (Huberdeau) continued to produce China clay, most of which was marketed with the paper trades. A description of the mine and developments was given in the August 11th issue of the *Canadian Mining Journal*.

During the first half of the year the quietness in the American pottery industries was reflected in reduced operations of Canadian feldspar deposits, but nevertheless there was sufficient movement to attract the interest of the general public, and a number of new prospects were tested. In the second half of the year business improved and resulted in increased shipments from the operating properties at Buckingham, Quebec, and Hybla, Ontario; and the Feldspar Quarries, Limited, started work at Verona. The Richardson Quarry remained under water, but a small gang was employed picking over the dumps. A new road was completed by the Ontario Government, from this quarry to the end of a new spur from the C. P. R. siding at Glendower.

Near Perth, Mr. A. M. Campbell opened up a promising deposit of feldspar and shipped some material. Dericks and suitable hoisting equipment were installed and stripping completed. On the Gulf of St. Lawrence at Manikauagan a large feldspar-pegmatite mass, which had been opened up a number of years ago, was again tested, and the operating company started building a suitable dock for shipping. At Toronto, the Feldspar Milling Company continued grinding feldspar for the Canadian trade, and a start was made at grinding quartz also. The increased duty on ground 'spar entering the United States has completely destroyed the possibility of grinding 'spar in Canada for sale in the United States.

# Contributions to the Economic Geology of Canada, 1922

By WYATT MALCOLM, Geological Survey.\*

Most of the papers and reports published in 1922 that contribute to our knowledge of the economic geology of Canada are the work of members of the staffs of the different Departments of Mines, Federal and Provincial. This is to be expected, since these Departments are organized and maintained in a large measure for the purpose of studying the economic geology and mineral resources of the country and presenting the results to the public in published form. From time to time very valuable contributions are made by mining engineers and economic geologists employed by the leading mining companies of the country or in private practice such, for example, as that made a few years ago by the staff of the International Nickel Company of Canada with regard to the ore-body at the Creighton mine. Papers of this nature are not so numerous as might be expected from men with such remarkable facilities for varied and detailed observations. The operating companies, however, are to be commended for the readiness with which they place at the disposal of the government geologists studying various mining camps the information that has been accumulated in connection with the development of particular ore-bodies.

The main contributions to economic geology are to be found in various government reports and in the form of short papers published in mining periodicals, more particularly in the *Canadian Mining Journal* and the *Bulletin of the Canadian Institute of Mining and Metallurgy*. These two publications have been the medium for presenting to the public concise and pointed articles setting forth the results of many investigations at a very early date after their completion.

No attempt is made in this paper to make a complete survey of the contributions made during the year to the economic geology of the country. Attention will be called to a few that appeal to the writer as outstanding.

## Gold Occurrences

On account of the importance that gold mining has assumed, particularly in the province of Ontario, much attention has been given to a study of geological conditions existing in the gold mining districts and in areas where prospecting for gold is being carried on. Percy E. Hopkins presents, in tabloid form, a wealth of information regarding the extent of mining operations in a report entitled "*Ontario Gold Deposits their Character, Distribution and Productiveness*." Cyril W. Knight, in presenting the results of a study of the *Lightning River Gold Area*, calls attention to two great belts of sediments in northeastern Ontario consisting of conglomerate, greywacke, and slate in which the most important gold deposits are found. The gold deposits have an apparent genetic relation to intrusions of feldspar porphyry and quartz porphyry. His advice to the prospector is to direct his attention to the search for these porphyritic intrusions in or near the great belts of sediments and carry on intensive prospecting in the vicinity of these. A third band of sediments on the south shore of Lake Abitibi, twenty-five or thirty miles north of the Lightning River area, is considered worthy of the attention of the prospector.

In a paper on the "*Shear Zones of Porcupine*" in the *Canadian Mining Journal* J. C. Murray presents the results of observations made in this camp, particularly at the Ankerite mine. The original silicification of the schists that form the country rock of the ore deposits was but one step in the processes preceding the formation of ore shoots. Shearing and structural deformation within the zones of schisting were pre-essentials of ore making. "Where intrusive porphyry has brought about only schisting and silicification the later but prime factor is missing. Schist may and does carry gold over wide areas in non-commercial quantities but so also do other metamorphic rocks. The missing factor is supplied when in addition to schisting, shearing and deformation also have occurred.

"In such cases the schisted zones have been fractured, usually, as at the Ankerite, at a low angle to both the strike and the dip of the schist. Following this, the fractures were filled by the agency of highly siliceous, enriched solutions of deep-seated origin". Tourmaline is plentiful in the vein filling but has not been found in the schist. The pyrite of the vein filling differs in physical properties from that of the schist; it is associated with high gold content in the former but is of low gold content in the latter.

The observations made by H. C. Cooke on the Larder Lake deposits are also of much interest. The gold deposits so far discovered in the Larder Lake area lie within bodies of dolomite which were formed, according to the author, by the dolomitization of sheared zones of the country rock.

"The gold occurring in the dolomite bodies occurs wholly in the free state. The examination of thousands of feet of drill cores and of the assay values later obtained from them which were placed at the disposal of the writer by the Associated Goldfields, showed that absolutely no connection exists between the concentration of pyrite, the only sulphide in the rock, and its gold content. It was shown when describing the dolomite bodies that the pyrite was deposited during the later stages of dolomitization, along with quartz, calcite, and fuchsite. The examination of ore specimens shows that the quartz of the quartz veins in the dolomite has been crushed, with production of numerous fine fractures, and it is in these fractures that free gold has been deposited in thin leaflets. The gold is, therefore, of later age than the pyrite and quartz.

"The movement that fractured the quartz veins prior to the deposition of gold was small, as the veins are rarely seen to have been displaced at all, and never more than a fraction of an inch. It was probably, therefore, a final result of the same strains that caused the progressive fracturing of the dolomite, previously described; and the gold-depositing solutions were probably the final exhalations of the underlying body of cooling magma the solution from which, as we have seen, formed the dolomite and quartz veins."

The pre-Cambrian formations in which the gold deposits of Ontario are found extend eastward into the province of Quebec. This area was mapped by the Geological Survey a number of years ago, but on account of the increasing interest shown in the gold possibilities a more detailed study of the geology was made during the summer of 1922, attention being given particularly

\* Published with the permission of the Director, Geological Survey of Canada.

to the location of small intrusions of acidic rocks with which the gold has been found to be genetically related. The results of these investigations have not yet been published.

Reports on a number of other areas in which gold mining or gold prospecting has been carried on have been published, such as the reports by P. E. Hopkins on the Schreiber district, E. Thomson on the Gendreau district, Ontario, and by E. R. MacKay on the Chaudière River district, Quebec.

Certain results of investigations by W. A. Johnston on the placers of the Cariboo district show that in parts of Antler and Williams creeks gold to the amount of at least \$1,800,000 exists, which may be recovered in a large part by dredging. A description is given also of the placers of Cedar creek that were opened up in 1922. The gravels are older than the glacial drift. They appear to be in place, but this is a matter that is open to question. If they are in place they indicate the occurrence of an old stream channel, the continuation of which should be looked for at about the same level as the discovered gravels.

#### *Silver and Silver Lead*

The results of a re-study by C. W. Knight of the economic geology of the Cobalt mining district were published in concise form early in the year. Facilities for the most detailed investigation were given by the operating companies. In summing up the situation he says: "So much for Cobalt's past. What of its future? Let it be said at once that mining will doubtless be carried on for generations, either in or around Cobalt, or in the outlying areas of Gowganda, South Lorrain, Casey, Montreal River, and elsewhere.

"The increase or decrease of mining operations is, it need scarcely be pointed out, somewhat dependent on the price of silver. Certain mines recently closed down are known to have important quantities of low-grade ore, either broken in the stopes or blocked out. Should the price of silver ever rise to a dollar an ounce, these companies could begin profitable mining once more.

"In Cobalt itself it is not at all likely that operations will ever again reach their past magnitude. Many of the highly productive properties have, indeed, been cut by such a veritable labyrinth of drifts, crosscuts, winzes and raises that there is little likelihood of discovering new vein systems of great importance, although smaller orebodies may be found. The properties west of Cobalt lake, for example, belong to this class of highly prospected mines. On the other hand, the Nipissing Mining Co. is in a class by itself. It has 846 acres in the heart of Cobalt, and has already paid \$24,000,000 in dividends. Part of this large acreage is still unexplored, and though the discovery of important vein systems is problematical, no one can foretell what further prospecting may bring to light. As late as last summer a new vein of high-grade ore was discovered on this property.

"There are some properties which merit further development, such as La Rose Extension, Colonial, Ruby, Genesee, and others. The drift-covered areas, too north of the Violet and Chambers-Ferland are attractive from a speculative point of view. The south end of Cobalt (the area known as Southeast Coleman) merits discriminating attention, where the upper contact between the Huronian and Keweenaw will no doubt be further explored as the years go by on account of the success obtained at the Beaver and Temiskaming mines.

"In the outlying areas, South Lorrain and Gowganda offer opportunities for prospecting, and the recent promising developments at the Keeley and Frontier mines, in south Lorrain, will encourage the expenditure of more money in this area."

Results of further studies by W. E. Cockfield on the geology of the silver-lead deposits of Mayo district, Yukon, and of a re-study of Gowganda silver area by A. G. Burrows, were published during the year.

The Geological Survey has been giving considerable attention to the mapping and study of the geology of the Coast Range batholith of British Columbia and of the intruded rocks. It is in this wideflung geological province that some of the most important ore deposits of western Canada have been found. A memoir appeared recently presenting the results of investigations carried on by S. J. Schofield and G. Hanson into the geology and ore deposits of the Salmon River district, where ore-bearing solutions emanating from the granite of the batholith during the final stages of cooling entered fissures and shear zones and at favourable localities formed ore-bodies of commercial size. "The ore-bearing solutions which formed the ore bodies on Big Missouri ridge evidently spread laterally along silver horizons in the tuffs and tuff conglomerates. In other cases, as at the Premier mine, the ore-bearing solutions found the sheared contact between the quartz porphyry sills and the tuffs a favourable place for ore deposition.

"A period of folding followed the above period of primary mineralization. Subsequently, processes of secondary enrichment concentrated the ores carrying high silver values in the neighbourhood of the fault fissures."

V. Dolmage, in presenting the results of a survey made of the coast and islands of British Columbia between Burke and Douglas channels, describes the Surf Inlet and Drum Lummon mines, and G. Hanson describes the economic geology of the Upper Kitzault valley including the Dolly Varden mineral zone. Further work on the Coast Range area was continued during the summer of 1922 by Dolmage and Hanson in British Columbia, and by Cockfield in Yukon territory.

#### *Petroleum Exploration*

On account of the interest that continues to be shown in the oil possibilities of western Canada, the Geological Survey has been doing considerable field work in mapping the geological formations and making a study of the structural features of the sedimentary rocks. The results of field work carried on by A. E. Cameron around the west end of Great Slave lake, by E. J. Whittaker along the tributaries of the Mackenzie below Great Slave lake, by G. S. Hume on the South Nahanni and Root rivers, and by M. Y. Williams on the east side of the Mackenzie between Simpson and Wrigley were published during the year. The results of the studies of certain structural relations in the Mackenzie basin were presented by D. B. Dowling. Further studies of the sediments of the Mackenzie River basin were made by Hume, Whittaker and Williams during the summer of 1922. Drilling operations in the prairie provinces have been closely followed by D. B. Dowling and by the Borings Division of the Geological Survey, in charge of E. D. Ingall, with a view to obtaining as much information as possible about the bedrock geology from samples furnished by well drillers. The importance of this method of working should not be minimized, for it is only through studies of this character that any knowledge of

the bedrock geology of a large part of the drift-covered prairie provinces can be obtained.

### Coal

Contributions to the geology of the coal fields of Canada were made by J. D. MacKenzie, W. L. Uglow, J. R. Marshall and John A. Allan. Mr. MacKenzie, in whose recent untimely death there passed one of the rare spirits in whom superior scientific capacity is combined with a charming personality, made a study of the coal measures of Cumberland and vicinity, Vancouver Island. The sediments in which the coal seams are found have been designated the Comox formation. They are of Cretaceous age. "During the stage of the accumulation of the Comox formation there were recurrent episodes when coal seams formed. In the Tsable River area five of these episodes may be clearly recognized by five usually quite distinct seams which can be correlated with some degree of assurance. In the vicinity of Cumberland the coal accumulation is not so clearly recognizable as belonging to distinct intervals, but even here there is evidence that the thicker coal seams at any rate were accumulated at four or five separate horizons. It is also generally, though not always, true that the thicker seams were formed near the base of the measures and that the seams formed later are thin and unworkable... The thickness of coal in any given seam may vary from a fraction of an inch to many feet, 25 feet of coal being the thickest obtained in any single seam. This, however, included a band of shale four inches thick, and the coal was soft and shaly. A solid bench of bright hard clean coal exceeding 30 inches in thickness is an unusual occurrence, though benches up to 35 inches are known. The upper of the two seams now being mined at Cumberland averages 3 feet 8 inches of coal; the lower one, about 100 feet below and near the base of the measures, averages 4 feet 2 inches."

W. L. Uglow in his description of the geology of the North Thompson River valley presents information regarding the coal fields near Chu Chua. Exact measurements are given of the seams being worked in this field. Analyses show that the coal is of low moisture content but rather high in ash. It is classified as low grade, low rank bituminous or low grade, high rank sub-bituminous coal. "The fuel ratio is that of a low rank bituminous coal; the moisture content suggests a high rank bituminous; the large amount of ash makes it a low grade coal; and the lack of prismatic structure and the tendency to split into sheets parallel to the bedding indicate a sub-bituminous coal."

"It seems probable that the original lignitic coal seams of this district were raised to sub-bituminous rank by thermochemical means; the heat having been supplied by Miocene lavas which it is believed formerly covered the coal measures. These lavas have since been completely removed by erosion."

The coal fields of the Kananaskis Lakes-Palliser River area are described by J. R. Marshall. The coal is of Kootenay age and is of the high carbon bituminous variety. On one property coal seams have been uncovered on almost all the west tributaries of Sheep creek in the upper six miles of its course. A tunnel driven 2,250 feet across the measures cuts 12 or 14 seams of coal ranging in width from a few inches to 39 feet. There are at least seven workable seams.

A report by John A. Allan on the Drumheller coal field, Alberta, states that four seams are being mined. These range respectively in thickness from 6 to 7 feet, from 1.8 to 4 feet, from 3.5 to 5.5 feet, and from 1 to 6.7

feet. The fuel ratios of the coals from these seams, obtained by dividing the percentage of fixed carbon, average respectively 1.36, 1.43, 1.44 and 1.44. The report is remarkable for the general excellence of the illustrations.

A study of the geology and structural features of the Pietou coal field was started by W. A. Bell of the Geological Survey in 1922. It is hoped that the field work, combined with the vast amount of information accumulated by the companies operating in this field, will lead to a clear understanding of the geological structure and be of assistance to the operators in future development work.

### Iron Ore

Field investigations in British Columbia for the purpose of obtaining much more detailed information than at present exists regarding the iron ore deposits of the province were started by G. A. Young during the summer of 1922. No report has yet been made. A report by G. A. Young on "The Iron-Bearing Rocks of Belcher Islands, Hudson Bay," appeared during the year. On these islands iron formation is known to occur in five bands. The total estimated land area occupied by the iron formation and by the volcanics overlying is 198 square miles. The total outcropping area of the iron formation is not greater than 15 square miles. The length of the outcrop exclusive of the problematical areas in the south part of Flaherty island and on the island to the west is estimated to be 119 miles, of which it is estimated only 10 miles all told are sufficiently well exposed to permit of unreservedly stating that iron ore beds are present or absent. No iron ore deposits of commercial value under existing conditions were seen after traversing in all 40 miles of the various bands. Highly ferruginous zones, however, were found, and where the formation was fully exposed two or more such zones were always in evidence. In thickness the individual zones vary from 10 feet to 50 feet. Analyses of samples representing thicknesses up to 24 feet and the examination of the material itself indicate that the zones are composed almost wholly of silica and iron oxides. Four representative samples gave on analysis the following results:

|                         |       |       |       |       |
|-------------------------|-------|-------|-------|-------|
| Silica . . . . .        | 32.52 | 46.48 | 42.12 | 38.60 |
| Metallic iron . . . . . | 44.96 | 35.42 | 37.80 | 39.10 |

### Lead-Zinc

F. J. Alcock describes in detail the geology of the lead-zinc deposits of Lemieux township, Quebec. The deposits are in Devonian shales and limestones intruded by porphyry and syenite. The sediments are folded, faulted, jointed and brecciated. The deposits occur in the form of veins and are believed to be genetically related to the deep-seated intrusive rocks of the area. Siliceous sulphide-bearing solutions from the magma in the later stages of its crystallization probably travelled along lines of fracture for considerable distances from their source and deposited their silica and sulphide content along fracture planes and in brecciated zones.

It is reported that a new discovery of a rich vein of gold, averaging from two to ten feet wide, has been made at Bontddu, near Barmouth, North Wales, in three lines of reef coming from the Clogau gold mines. Near this discovery recent floods have disclosed a reef of gold-bearing quartz over thirty feet wide.

## ALASKA MINERALS IN 1922

The mineral production of Alaska for 1922, as reported by the United States Geological Survey, is \$18,250,000. As a large part of this output was from districts contiguous to Canadian territory in the Yukon and British Columbia, where similar mineral deposits are under operation or are being developed, it has a special interest for Canadians.

Gold was produced to the value of \$7,730,000. Of this \$4,100,000 was from placers. The total output of Alaska to date is \$230,000,000, which is twenty millions more than the total output on the Canadian side. As in the Yukon, dredging and hydraulic ground sufficient for many years of operation has been determined.

The Treadwell mine continues to be the principal gold producer from lodes, though its operations are now restricted on account of the flooding of some of its mines. The Alaska Juncau mine, which treats at a profit ore than contains less than a dollar a ton as it comes up from the mine, has been saved from financial disaster only by some clever and straightforward management. With the aid of a number of smaller mines, the production of lode gold during 1922 was brought up to \$3,600,000.

In the Salmon River area, adjacent to the Portland Canal gold-silver area of British Columbia, there are as yet no producers; but the success of the Premier mine has stimulated a good deal of active development, and the outlook is hopeful.

Copper is produced mainly at the well-known Kennecott mines, opened in 1911. The production for 1922 was 68,000,000 pounds, which raises the total that Alaska has now produced to 740,000,000 pounds.

The Transvaal gold output for November 1922 amounted to 764,476 fine ounces, as compared with 770,159 fine ounces for October 1922 and 704,236 fine ounces for November 1921.

The Bureau of Standards in Washington has proved to be a valuable training-ground for specialists in the various industries. During the twenty-one years of its existence it has trained 574 technical graduates for an average period of 2 1-2 years before their departure. The positions to which these men have gone are, on the average, most desirable and most responsible, as well as well-paid.

During 1922 the United States has produced 400,000,000 tons of bituminous coal, which is about equal to the 1921 production, but from 100 to 150 millions tons below the output of the preceding four years. The anthracite production has been slightly over 50,000,000 tons, which is about 40 million tons below the normal output.

The new feldspar mill at Keene, New Hampshire, which embodies features that are new in the grinding of feldspar, is giving excellent service. The general plan of this mill is that recommended recently by Mr. R. B. Ladoo of the Bureau of Mines, Washington, to supersede the archaic methods now in vogue.

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

Summary Report of the Mines Branch, 1920.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:

**Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

**Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

**Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

**Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

**Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**

Summary Report. The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

THOS. W. GIBSON,  
Deputy Minister of Mines,  
TORONTO, CANADA.

GARDEN CITY PRESS, GARDENVALE, QUE.

The Home of  
The  
Canadian Mining Journal  
GARDENVALE, QUE.

Garden City Press is situated on the Toronto to Montreal and Ottawa to Montreal lines of the C.P.Rly. and G.T.Rly., adjoining Macdonald Agricultural College. The railway station, telegraph and express office on either line is Ste. Annes, but the post office, which is located in our own plant, is Gardenvale, Que.

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

**MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC**

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, \$76,177,403; Lode Gold, \$105,557,977; Silver, \$55,259,485; Lead, \$48,330,575; Copper, \$166,393,488; Zinc, \$21,848,531; Coal and Coke, \$225,409,505; Building Stone, Brick Cement, etc., \$34,072,016; Miscellaneous Minerals, \$1,210,639; Making its mineral production to the end of 1920 show an

### Aggregate Value of \$734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for the year 1916, \$42,290,462; for the year 1917, \$37,010,392; for the year 1918, \$41,782,474; for the year 1919, \$33,290,313; 1920, \$35,543,084; 1921, \$28,066,641.

### Production During last ten years, \$336,562,897

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

**VICTORIA, British Columbia.**

## Canada Foundries & Forgings LIMITED WELLAND ONTARIO

# MORSE CHAINS

*A few of the Morse chains in use at the Raymond Lead plant*

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.

*Write for Booklet*

CANADIAN AGENTS

## Jones & Glassco, Regd.

MONTREAL, TORONTO.

O. W. Ludwig, Plant Superintendent of the  
Raymond Lead Co., Chicago, says:

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful—and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

## A Basis of Confidence

This Bank's strong financial position assures ample protection to those making it a depository of business funds. The paid-up capital and reserve, and assets of over \$126,000,000 constitute a sound basis of confidence.

Established nearly fifty years ago the Imperial Bank has expanded side by side with the development of Canada's mineral resources.

With over 200 branches covering the Dominion and strong affiliations abroad, this Bank is enabled to fulfill every requirement of modern banking, domestic or international.

### HERCULES PINE OIL SAVES YOU MONEY

Experienced flotation operators are finding pine oil the most economical reagent they can use. It is the best frother known and recovers more concentrate than any other. It is the cheapest flotation oil when compared with others on the basis of Hercule Pine Oils are steam-distilled and consequently superior to oils distilled by other methods. They are produced under strict chemical control and are made to conform rigidly to specifications that will meet your requirements. A comparison of samples will prove their superiority.

Write for booklet No. 200 which gives specifications for our standard grades.

## THE TURBINAIR "SLUSHER" HOIST.

For handling "slushers" or scraper loaders underground, or at stock piles or tailing dumps, this NEW SULLIVAN DOUBLE DRUM HOIST secures rapid work with power economy and convenience.

In slushing, one drum hauls in the load, the other returning the scraper by a tail rope.

The motor runs continuously, and the clutch on each drum is thrown in or out with perfect control at all times as needed. Either drum is capable of hoisting 2,000 pounds vertically on 75 pounds air pressure, the same as the single drum hoist.

The light weight, [555 pounds,] and compactness of the Double Drum Turbinair make it convenient for use in sub-levels or other work in places that are hard to get at. The hoist is bolted to a skid or timber or mounted on a turntable if desired.

*The work of the miner has one great distinction over most other commercial enterprises. He does not merely divert wealth from some distant channel to that one in which he is interested, but he actually creates wealth, by bringing into use material which otherwise would remain inert and useless — J. B. Porter — 1897*

### A "DANGER SIGNAL"

Moved by Mr. W. S. Johnson, and seconded by Capt. J. G. Ross, that Council were gratified to feel that the work of the Institute was of sufficient interest and value to warrant financial contributions from mining corporations in support of Institute activities and that the Council are pleased to accept such contributions that are offered in the same way and under the same conditions as any grants made by Federal and Provincial Governments. Council desires to record its appreciation of the President's (Mr. W. R. Wilson) offer to recommend that his Company make such a donation, and hope that his example will be followed by others doing likewise." The motion was carried.

This is a minute of the last meeting of Council of the Canadian Institute of Mining and Metallurgy, open for every member of the Institute to read in the minute-book at Headquarters. We print it here because very few of the members will have an opportunity of reading it in the original; and we draw attention to it because we consider it to be a move fraught with very grave danger to the Institute.

As expressed in the above motion, the receipt by the Institute of donations of money from mining companies is merely "quid pro quo", and the Institute is only getting its deserts. The parallel with subsidies from governments also is convincing, so far as it is stated. But it is what is not stated by the motion, and that would escape the notice of the casual reader, that is ominous of danger not only to the dignity of the Institute but to its useful existence.

On numerous occasions, both public and private, the virtual control exerted over the Institute by the Federal government by virtue of its annual contribution to the funds has been a matter of discussion. Many a motion designed to influence government policies or the expenditure of public funds has felt the curbing effect of this control; and many a member has wished, both audibly and beneath his breath, that the Institute were free to speak the unfettered truth. Still, it has been expedient to bear the shackles of this mild form

of government control for the sake of the undoubted benefits that result.

The present motion of Council has laid the Institute open to be bound, hand and foot, by fetters that can confine it much more closely than any Government subsidy, could ever do. At the worst, a government subsidy can be the means of impressing upon the Institute the will of a public servant whose poor judgment or self-seeking has led him astray; but he can be removed from public office and his influence thus nullified in a moment. At the worst, the acceptance of a subsidy from a mining corporation whose motives are not of the best can constitute an eternal obligation, from which the Institute can never escape so long as the company's management wishes to impose its will. There are undoubted facts, as a little reflection will show; and though they state the extreme to which the Institute could be controlled by financial benefactors, this extreme case must be considered in judging of the position in which the Institute is now placed by Council's action.

It were far better that, if gifts of money are to be received, they should come from private individuals. It is a well-known fact that, on this continent at least, a man in his private capacity is much more likely to be scrupulous than when he is acting on behalf of a company or corporation. The "soul-less corporation" is not a mere figment of the imagination; it is a factor in modern business that is clearly recognized and discreetly dealt with by men of business. In the specific instance with which Council have dealt in their motion, the individual comprises the corporation, and thus the Institute is safe. We suspect that the personality of the donor in this case and his undoubted sincerity and good will have prevented Council from examining the general case in a searching way and thus have caused them to make this grievous error in judgment.

The Canadian Institute of Mining and Metallurgy has a fine inheritance from its founders. If this inheritance is to be handed down unimpaired to our successors, the members in general must repudiate this action of their Council. Let us beware lest we sell our inheritance for a mess of pottage.

## STRAWS

The wind bloweth where it listeth, but our meteorological savants record and even predict its every whiff. The "higher development of common knowledge," to use Herbert Spencer's phrase, has enabled scientists to discover and utilize the laws that govern the movements of the wind.

The closer study of international finance has given definite significance to the apparently arbitrary currents and cross-currents of the interchange of gold and silver.

In the case of gold, it is common knowledge that the United States, through causes incidental to the Great War, has become the largest importer of that precious metal. But it is not yet widely known that a radical change is setting in. During the first eleven months of the year 1921 our neighbor's imports of gold amounted to \$660,000,000; but during the first eleven months of the year that has just ended, the gold imports totalled only \$249,000,000, which means a decrease of 62 per cent. Such a falling-off is unprecedented in any year for the past decade. It is fraught with greater meaning, however, in view of the fact that exports of gold are growing at such a rate that financiers predict that they will soon exceed imports in volume. It is thought that not even payments on account of the allied debts will effectually counteract this outward flow.

There are too many factors entering into the situation to permit of a simple analysis. But one thing is evident, and that is that tremendously increased industrial activity in other countries is reacting on the United States. It would seem, also, that the new tariff regulations that our neighbor has put into force have stimulated exports of gold. Be that as it may, the United States is gradually approaching its pre-war status in the matter of gold reserves.

The international position of silver is quite as interesting as that of gold. Provisional estimates of the world's consumption of silver during the year 1922 place it at 307,000,000 ounces. The world's output for the year was only 200,000,000. Consumption in the Far East, China and India principally, amounted to about 220,000,000 ounces.

The expected output for the coming year, provided the lead and copper markets remain firm, is put at 225,000,000 ounces. The proviso is necessary, since approximately 70 per cent. of the world's production is derived as a by-product from copper, lead and zinc mines. The expected demand for silver during 1923 is placed at 280,000,000 ounces.

Thus, it seems, there will be a cumulative shortage of about 160,000,000 ounces. The deficiency between consumption and output was made up, in part, during the past year by the conversion of European coinage into bullion. How far this may be a factor in meeting

the current year's demands is not known. But it is certain that China and India will soon have to resume coinage of silver on a large scale.

Altogether the outlook for silver is very bright indeed.

For gold mining it need only be said that all things seem to conspire to encourage it the world over, and in no country to such an extent as in Canada.

## THE NON-METALLIC MINERALS

It is a truism that the metals, and particularly the precious metals, tend to monopolise the attention of those interested in the mineral industry. This is a tendency to be mildly, but actively and continuously, combatted if we are to have a well-rounded mineral development.

During the past six months the *Journal* has paid a good deal of attention to feldspar. Feldspar is only a moderately important mineral; the annual production of raw feldspar on the North American continent has a value of only about a million dollars. But it has been convenient to treat the subject of feldspar at some length, and the discussion (which still continues) will, we hope, prove to be of considerable benefit. Today, for instance, Mr. R. F. Segsworth, who has investigated with great care during the past three years the possibility of a profitable export trade in feldspar to England, points out that the rather pessimistic conclusions of Mr. Davis, and of Mr. Spence, who examined the case on behalf of the Mines Branch, Ottawa, can hardly be based on authoritative and recent data. We have read the correspondence to which Mr. Segsworth refers, and find his conclusion inevitable from the data presented. Indeed, one correspondent representing a large and long-established English firm commenced his correspondence with Mr. Segsworth with the statement that an export trade in Canadian feldspar could not be conducted profitably, and after a thorough investigation was compelled to reverse his decision, and was impelled to set down some of the hopeful statements quoted in the letter we print today. We hope there will be more discussion of this point, which will help still further to illuminate the question.

What we wish to point out particularly today, however, is that feldspar is only one of the numerous non-metalliferous minerals that we have in abundance in Canada, whose present neglect or merely partial use is due to lack of well-directed human initiative. We have rock salt, gypsum, magnesite, soapstone, chemical limestone, quartzite, clay of all grades, bentonite — all waiting to be turned into cold cash by men of creative imagination and managerial ability. All of us interested in the mining industry, should aid such men to vision such opportunities for the commercial use of these minerals as may exist, and then should give

them all the assistance possible to bring the vision down to earth.

The *Journal* includes among its New Year's resolutions the determination to lose no opportunity of forwarding the interests of non-metallic mineral production in Canada.

#### FELLOWSHIP FOR ASBESTOS RESEARCH

During recent months *The Canadian Mining Journal* has on numerous occasions pressed the importance of industrial research to Canada. We have now the pleasure of noticing a move on the part of a prominent mining corporation that is very much to its credit, and that speaks well for the spirit in which its operations are directed. The announcement is made in the December issue of *Asbestos*.

Consolidated Asbestos, Limited, whose mines are in the Thetford district of Quebec and whose head office is in Montreal, have established at the Mellon Institute of Industrial Research, University of Pittsburgh, a fellowship, to be known as the "Chrysotile Fellowship." The researcher holding this fellowship will apply his efforts toward extending the present uses of asbestos and finding new uses. Consolidated Asbestos have invited the co-operation of all and sundry interested in the asbestos trade in providing problems and ideas for the researcher to work on, and express the conviction that this general service to the industry as a whole will, in the long run, amply repay them for the funds thus invested.

This move shows public spirit on the part of the directors of Consolidated Asbestos, as well as an appreciation of the trend of the times in industrial management. It also is, most decidedly, good business to invest a modest sum annually in this way. They are, we believe, the first among Canadian mining companies to take this step, and we offer them our hearty congratulations on being at the head of what we hope will be a procession of mining corporations that will follow their lead.

There is one aspect of this case, however, that cannot but be of grave concern to any thoughtful Canadian. The "Chrysotile Fellowship" is to be held at the Mellon Institute in Pittsburgh. This is the logical place for it to be held. Why? — because there is no corresponding institute of industrial research in Canada where the researcher could employ himself effectively. It was precisely to meet this need that the Advisory Research Council at Ottawa proposed, three years ago, that a National Research Institute for Canada should be founded. It has not been founded, nor has any alternative provision been made to provide the facilities for general industrial and scientific research that are so urgently required. The founding of this new Canadian research fellowship in an American institute is a definite instance to prove the present

lack of the required facility in Canada, and to indicate the pressing need for establishing it immediately.

#### EDITORIAL NOTES

In "Letters from Porcupine," in our issue of November 17th, it was stated, as an instance where "high grading" is a venial sin, that "a Canadian professor was observed surreptitiously jamming a few of the choicest pieces into his side pocket," from the dump of a northern gold mine. On the face of it, this remark is meant to be a shrewd hit at the well-known specimen-collecting tendency of all professors. We find, however, after some private discussion, that the implication in this case is quite without foundation; the professor in question did not, on that or any other occasion, appropriate choice samples as stated. We therefore take this occasion of denying the allegation; we cannot "defy the alligator," because we have involved ourselves with the writer, by allowing the statement to get into print in our pages. The paragraph has been taken seriously by a number of our readers, and has been interpreted in a light that did not strike us at all on first reading, else it would never have passed the editorial censorship. We regret that any statement should have been circulated through our agency that could be construed as a reflection on the character of Canadian professors — the particular professor having remained un-named and many therefore, being involved.

Dr. Allan's excellent resumé of the progress of mining in Alberta during 1922, which we publish today, arrived too late for inclusion in the annual review number last week, for which it was intended.

#### THE ARTIFICER

The canopy of night is cobalt, sprent  
With silver curiously wrought. The pent  
Gold of the rising and the setting sun  
Is only little part of what is done  
By the Artificer whose high delight  
Is His own handiwork in making bright  
Earth, sea, and sky with colours from the ore  
Which Nature's mystic crucibles do pour.  
The opalescent miracle of dawn;  
The amethystine sky when day is gone;  
The emerald green of earth when Spring is young;  
The crystal wonders of the North, unsung;  
That iridescent marriage of all metals,  
The Northern Lights; the colouring of petals;  
The bloom on woman's cheek; the very blush  
That crimsons mine when I am writting slush;  
All come from Nature's smelter: She's a miner.  
Likewise a metallurgical refiner

# The Rehabilitation of Gold Mining in Nova Scotia

A. E. FLYNN,\* A. R. S. M.

At the present time much thought is being given to the possibility of the re-establishment of gold mining as an industry in this province. Questions such as these are asked: Is the gold industry dead, or only dormant? What is the cause of the present inactivity? Can anything be done to improve matters? Why is no effort being made to look into the situation? There is a decided feeling that we have allowed a valuable industry to fall into a decline and have done nothing to succour it.

## *Workable Ore Bodies Available*

The exploitation of a natural resource such as gold is of great importance to any country and should be given every consideration. This consideration has not been given to the industry in Nova Scotia for the last fifteen years, during which time it has been most needed. Since gold was first discovered 60 years ago the average annual production has been 10,000 ounces while it has amounted to over 31,000 ounces in one year. Since 1905 the production has gradually fallen from the average figure to practically nothing. When we consider that there are many mining properties in the province showing bodies of workable ore that are not being worked, the situation certainly calls for attention. The fact that we have workable bodies of ore awaiting development and other deposits that have a good chance of becoming workable shows that the industry is not dead but only dormant.

## *Reasons for Failure*

In approaching the question of the rehabilitation of the industry we must first consider why the former operating mines have ceased operation. Stated briefly we can say that they ceased to pay; that is, they could no longer produce gold at a profit. This does not necessarily mean that they have failed as mining ventures, as they may have made ample return to the operators during their existence. However, in this Province there is no hiding the fact that the great majority of the mines have failed. It must be called to mind that for a mine to be successful it must return to the operators an amount equal to their original investment plus a comparatively high rate of interest on this sum. Not many mines in Nova Scotia could claim this record.

There are many circumstances that lead to mine failures and I have made an attempt to collect and classify them, with some remarks on the circumvention of their effects. The events that cause failures may be said to come under two general classes, first, those that are beyond human control, and second, those that can be controlled; but as human control is so involved I prefer to consider the following classes—1. Geological; 2. Calamitous; 3. Market conditions; 4. Management; 5. Finance.

**Geological.**—Chiefly depletion of ore. (a) The ore may become poorer in grade, in which case costs must be lowered, preferably by improvement in mining and metallurgical methods. (b) Boundaries of ore-body reached, (b-1) artificial boundary (claim lines), (b-2) natural boundary (cessation of values, faults, pinches, etc.) in which case neighbouring land or mining rights must be acquired or geological investigation and exploration carried out.

**Calamitous.**—This would include cave-ins, flooding, fire, snowslides etc. Insurance and foresight can usually prevent the consequences of these from becoming fatal.

**Market Conditions.**—As gold has a standard value it is not affected. Supplies fuel (or power) and labour are affected, as are also any by-products of the ore.

**Management.**—I use this term in its broadest sense to include direction of affairs and policy. Bad management is one of the chief causes of failures and covers a big field. It would be out of place in this outline to attempt to enumerate the different ways in which the shortcomings of a manager can ruin a mine. They can all be covered by the word incompetence and, at times, dishonesty. It is important to note that when the management makes no effective effort to counteract the previously mentioned adverse conditions, the management must share in the responsibility for failure. This is the reason why in so many cases poor managing must stand the blame. The evidence is often seen in this Province in inadequate equipment, inefficient methods of mining and milling and lack of development policy, with the resultant high costs and a large part of the values going to waste.

**Financial.**—The mine may be over-capitalized or under-capitalized. It often happens that too much of the capital goes to the promoters or brokers and too little to the mine. Or again, in prosperous times excessive dividends are distributed, leaving no reserve for hard times. Mines frequently start up before their financing is completed and when the financing campaign fails there is often a loss in reorganizing and more often a complete failure of operations. Most fraudulent enterprises come under this heading. It is also probable that the majority of cases in which law-suits tie up operations would be included in this class.

In looking over the annual reports of the Mines Department of Nova Scotia I have picked out the different reasons given for the decline of the gold industry by the various engineers temporarily employed by the government. They are—

- Too many shafts.
- Expense of pumping too heavy.
- Stopes too wide.
- Too much overhead expense.
- Too many bogus companies and wildcatting.
- Attraction of capital and men to other booming camps.
- Insufficient capital.
- Unintelligent direction of operations.
- High cost of fuel.
- Lack of prospecting.
- Cave-in (in one case)
- Too much spent on surface equipment and not enough on underground development.
- Scarcity of water (in one year).
- Veins worked are too small or too low in grade.
- War-time conditions.

It will be seen from the above list that practically all the causes given are those that come under human control and that most of them can be attributed to bad management. This is significant. It is also a grave charge against the mining profession that will be resented by many. However, it must be borne in mind that the policy is often dictated by those who provide the capital, and these men do not usually belong to the mining profession.

## *Mr. Rickard's Report*

The only attempt to make a thorough investigation of the decline of the industry was made by T. A. Rickard in

\* Professor of Mining, Nova Scotia Technical College.

1907. His conclusions were that mining would only be successful as small units, involving little outlay of capital and operated by practical miners. This was disappointing to those who had been pinning their faith in large organized stock companies in the belief that the larger the scale of operations the less the cost of producing gold. They did not appreciate the fact that a large scale of operations is only justified when a large body of ore is proven. One cannot lose sight of the fact that, taken on the whole, our veins are narrow and the ore-shoots are small and are often scattered and hard to find when they do not crop out at the surface. A heavily capitalized mine could by extensive underground exploration bring the "blind" ore-shoots to light, but experience seems to show that the values extracted from the ore would only rarely pay for its finding and extraction. Conclusion similar to Rickard's have been arrived at by several engineers who have made a study of the situation, though there are others who do not hold the same views.

We cannot escape the fact that all the formerly operating mines (both large and small,) are to all intents and purposes dead, and the records they have left behind them are not encouraging. The Mines Department figures show that the average value of the crushed ore throughout the 60 years is only about \$8.70 per ton. This figure becomes much smaller if translated into value per ton mined, as the narrow veins entail the mining of a considerable proportion of worthless material that is not crushed. Taking these low values into account and considering the fact that a lot of money was invested in bogus companies and other mines that did not attain to the producing stage, one is tempted to say that more money has been put into gold mining in Nova Scotia than has been taken from the ground. However the figures of the Mines Department must be interpreted with strict regard to the fact that much of the gold was lost by poor extraction and that much low-grade material was mined that should not have been mined or crushed, while it is well known that some operators, to save the two percent royalty, did not make full returns, and also that the miners pilfered much gold.

Turning to the brighter side of the picture we can say that certain of the mines were successful, that we have exposures of payable ore awaiting development and that we can profit by past mistakes and modern methods. We can see a chance for the recuperation of the industry so long as it follows a carefully chosen policy and receives the proper guidance. The keynote of the situation is proper guidance; without it former mistakes will be repeated. We must provide the most competent management.

#### *Competent Guidance for Small Operators*

Whether the future of the industry depends on small mines or not, the mines will have to start up in a small way. It is idle to state that we have "Hollingers" ready to be worked. The Hollinger mine was not made in a day or in a year. If our small mines develop large quantities of ore they will then develop into large mines; but this can not be judged from the surface or from shallow workings. The chief thing we have to keep in mind is that small operators cannot afford expert management and without it they will go the way of their predecessors. The Government, through the Mines Department, can and should provide the necessary guidance. The Government, and the Government only, can provide the means for the rehabilitation of the industry. The Mines Department has done very little for the mines in the past and this is one of the grievances of the miners, who claim that they get nothing in return for their two percent royalty on

gold. On checking up the special provisions that may be said to assist the mining industry I find there are two. There is the Deep Mines Act, which assists deep shaft sinking and crosscutting; but this of no avail to the small operator. Then there is the provision under which the Mines Department may, when authorized by the Governor-in-Council, purchase boring machines, crushers and other mining machinery for testing deposits. The boring machines they have got and they are excellent for everything but gold. The mining machinery has never been purchased. In this connection I should like to point out that the Province has an eminently suited plant for testing small lots of ores in the Murray Mining Laboratory of the Nova Scotia Technical College. This should be taken advantage of, as I know there is even in these depressed times a big demand for the testing of ores. We can thus see that the small operator receives neither help nor encouragement and his problems and wants are little understood by his local Government. All his geological information he obtains from Ottawa. If he wants to know what values there are in the old dumps and how they may be best extracted, he can again obtain his information from Ottawa, not Halifax.

#### *A Neglected Industry*

The time has come for an accounting, and judging from results we can say that nothing effective has been done to prevent the decline of this basic industry. The Maritime Provinces as a whole have neglected their Mining Departments, with the result that the metal mining industry is not supported as it should be. This has led to a belief abroad that the mines of these Provinces are not worth considering. It is not an exaggeration to say that when promoters or capitalists are presented with similar mining propositions, one in the Maritimes and one in any other Province, that one in the former Provinces receives practically no consideration at all. Many of us have observed this. At present outsiders have a lack of confidence in metal mining in the Maritimes. Something must be done to remedy matters. We should follow the example of the other Provinces, who take good care to foster both prospecting and mining. Other Provinces are liberal with free grants of claims to original discoverers of mineral deposits; they will not allow claims to be held unless they are worked; little or no royalty is collected; a limited number of free assays are granted with each claim; ores are tested and small lots of concentrate are purchased; so-called Blue Sky laws are being enacted to eliminate fraudulent operations; and "high grading" laws are in force. Most important of all, they have Provincial Mineralogists, Geologists and Mining Engineers. It is the work of these men that does most for the development of their mineral resources.

#### *A Practical Suggestion*

Nova Scotia has great need for this addition to her Mines Department. As her geology has been so ably taken care of by the Dominion Government, her immediate need is for a Provincial Mining Engineer irrespective of the Deputy Minister, and he should be available as a consulting engineer to the small operators. By this means the necessary guidance can be provided for these small operators, and so the chief cause that has held back our successful business and professional men from taking up mining as an investment will be removed. Such men cannot be expected to know enough of mining to make a success of it on their own initiative, yet they are the ones who have provided the capital (and often the policy) in the past and will provide the capital in the future. We also need up-to-date reports on all our mineral resources and these should be distributed freely. This will do much

to create a new interest and confidence in mining in the Province.

In a general way the conditions necessary for the re-opening of mines are one or more of the following:

- Readjustment of market conditions.
- New mining methods and equipment.
- New metallurgical methods and equipment.
- New management and policy.
- New capital.
- More geological knowledge.
- More favourable laws.

Mining science has made long strides since Nova Scotia gold mining was in its prime so that if the Government will enact favourable provisions to foster and guide the industry we can be assured that it will re-establish itself and be on a firmer footing than formerly. The world is continually going farther afield to find gold and with the increasing difficulty of finding new mines more attention will be given to districts that have produced gold in the past.

A well manned department is also essential for the development of our other mineral resources, which are at present being neglected. Reference can be made to the oil shales of Pictou county, where a minimum of 400,000,000 barrels of oil can be obtained from a tract of land of about 10 square miles. The oil shale industry when developed will be comparable to the coal industry, yet nothing is being done to encourage its development. We have many other mineral deposits, specially non-metallic, which if properly exploited will give rise to staple industries and bring Nova Scotia to its proper position among her sister Provinces.

The Maritime Provinces are alike in their neglect of their mineral resources. They are acting together in their hydro-electric development and in University education to their mutual advantage. They have much in common. Could they not to advantage co-operate in the development of their mineral resources?

## Letters From Readers

*Campbell-Corless*

The Editor, Canadian Mining Journal.

Sir:

For many months now the Campbell-Corless controversy has waged in the *Canadian Mining Journal* and the *Bulletin of the Canadian Institute of Mining and Metallurgy*. So far it has been instructive, except when Mickle introduced mathematics, and it was also a serious discussion until J. C. M. made it an excuse for that "adjuration" in your issue of December 22, 1922. I think every unbiased reader will agree that both Mr. Campbell and Mr. Corless are absolutely correct and that both have proved that they are correct. That is, they are correct up to a certain point and then both make the same mistake: they take in too much territory. Corless' deductions are reasonable for the North Central mineral-bearing part of Canada with which he is familiar, and Campbell's reasoning is correct for the Western mineral-bearing portion of Canada with which he is familiar. As impure mathematics and worse poetry have been introduced into the discussion it is time to call a halt or the discussion will degenerate into an argument such as the benefits of the O. T. A., or Haultain's infamous query, "Why is a Geologist?" The discussion has proved one thing about mining engineers, even the top notchers, which I think ought to be emphasized, and that is that they, like less important individuals, are, in their mental attitude, entirely governed by their personal experiences. We are all familiar with the jibe of the near-engineer, "The mine makes the man." Equally true is it that a man's personal experience decides what his mental outlook shall be, whether he shall be an optimist or a pessimist. Take Corless and Campbell. Both graduated from McGill. Corless went to Sudbury and associated himself with the Mond Company, at that time operating in a small way. The uses of nickel increased, the ore-bodies proved year by year to be larger and richer than hoped for. Corless rose from underground foreman of the Victoria mine to Managing Director of the Mond Nickel Company, now one of the strongest metal companies in the world. During the past twenty years, in addition to seeing the marvellous growth of his own company, he has seen the Sudbury district prove to be one of the greatest store-houses of mineral wealth in the world, with a century's supply of ore in sight. During the same period Cobalt, one of the greatest silver camps in the world, was discovered

a few miles from his own district and, a little further away, Porcupine and Kikland Lake appeared on the horizon and in a few short years the Hollinger took its place as the leading gold mine in the world. No wonder Corless throws his hat in the air and shouts, "There is no limit."

Now follow Campbell. Looking into the future and realizing what Montreal would be in 1922, he tried to get as far away as possible and only the Pacific Ocean stopped his flight. He associated himself with the Granby Company and from that day to this it has been one long, heart-breaking struggle to make payable ore out of mineralized country rock. When he would succeed in cutting down costs till a profit was in sight, the mine would bottom and the same thankless attempt would have to be made elsewhere, generally with the same result. And what of his neighbors? The same story, only more so. Campbell has only seen one first-class mine, the Premier, discovered in the past twenty years in his province. Is it any wonder that after twenty years of such disappointments and disillusionments he looks into the future and says, "The worst is yet to come?"

Is it not improbable that if twenty years ago Corless had gone to the Granby and Campbell to the Mond, Mickle today would be proving by Dr. Coue's well-known mathematical law that every day, in every way, Corless is getting wronger and wronger!

Toronto, Ont.

X. B. C.

*Alberta Provincial Geological Survey*

The Editor, Canadian Mining Journal.

Sir.—

In order that any misunderstanding that might have arisen, may be cleared away, I wish to draw attention to the editorial that appeared in your *Journal*, September 29, 1922, under the title "The Provincial Geological Surveys." In this editorial your remark on the Alberta Geological Survey is worded in such a way that the reader is apt to get a wrong impression of what was meant. I refer to the words, "are somewhat shrouded in mystery." I have been instructed by the Scientific and Industrial Research Council of Alberta to write you a word of explanation on this matter. It would have been fairer to the province to have stated that Alberta was one of the provinces that

have not yet been given control over their natural resources. Under these conditions, one could hardly expect the province to organize a department under the title "Provincial Geological Survey." It is the duty of the federal geological survey to investigate the geology of all of the provinces and more attention might be given to those provinces that do not control their mineral resources.

In 1919 the first step was taken by the provincial government to compile data regarding the mineral resources of Alberta. This can be regarded as the beginning of a geological survey. In the following year the "Scientific and Industrial Research Council of Alberta" was organized and a department was started under the roof of the provincial University but directed by the Council. The Hon. J. L. Côté, late Provincial Secretary, was largely responsible for the organization of this department. The original Council consisted of the Provincial Secretary under whose department the appropriation for this work was administered; Mr. J. T. Stirling, Chief Inspector of Mines, representing the Government; Dr. H. M. Tory, representing the University; Professor N. C. Pitcher, Mining Engineer; and Professor J. A. Allan, Geologist.

In 1921 the Council appointed Mr. Edgar Stansfield, Chief Chemical Engineer, and Dr. K. A. Clark, Research Engineer on road materials. Mr. Stansfield was appointed to the Council as Honorary Secretary, and with the change of government, Premier Greenfield as Provincial Secretary, became chairman of the Council.

Up to date two annual reports have been published by the Scientific and Industrial Research Council. These describe the character of work carried on within this department. Investigations are being carried out under the following divisions: fuels, including sampling, screening, storing, burning, carbonization, and purification of coals and boiler trials on the coals tested; investigation of road problems and the extraction of bitumen from the Athabaska bituminous sands for the purpose of road dressing; preliminary investigations on mineral deposits; investigation of forest products.

The geological division has published annual reports on the geology of certain areas. Three have already appeared, beginning 1919, and the fourth annual report is in the course of preparation. The first two reports contain notes on the various minerals that are known to occur in this province; the third annual report deals with the geology of the Drumheller coal basin, which is the most important district in Alberta producing domestic coal today. The fourth annual report is now in preparation and contains the results of detailed investigations carried out in two fields.

When the time comes that the province controls its mineral resources, there is no doubt that the geological work, at least, will be carried out in accordance with the general practice adopted in other provinces. It is therefore not the intention of those concerned to "shroud in mystery" the geological work which is being carried on in Alberta under the authorization of the provincial government.

Edmonton, Alberta.

John A. Allan

*Editor's Note.*—The paragraph referred to in the *Journal* of September 29th is as follows.—"Alberta has now a well-established geological survey, though its activities are somewhat shrouded in mystery under the name of its executive body, the Scientific and Industrial Research Council of Alberta. What we would judge to be a systematic and sustained effort has been commenced by officers of this department with the object of making immediately available the aid of geological service in the commercial development of the province's minerals."

### *Export of Feldspar to Britain*

To the Editor, Canadian Mining Journal:  
Sir:

Mr. N. B. Davis's letter published in your issue of December 29th, contains statements so contrary to ascertainable facts that I am quite at a loss to imagine where and how he gathered his misinformation.

To show the appalling inaccuracy of some of Mr. Davis's positive assertions I have but to establish a "deadly parallel" between them and the authoritative and committal statements of responsible English firms who are ready to do business. Circumstances do not permit of my quoting any names, but I shall at any time be glad to exhibit to you, Mr. Editor, the originals of all letters from which quotations are made. I may add that the letters, all from firms of high standing, demonstrate that the impression that Mr. Davis seeks to convey concerning the overseas market is astonishingly wrong — how wrong your readers can judge for themselves.

*Mr. Davis*

What feldspar is now being used in Staffordshire is being laid down at the mills for approximately \$10.00 per ton.

*The Other Side*

A fair price for lump feldspar today is \$26 to \$40 per ton and for the ground in bags, \$15 extra ex-store English port.—*From letter dated Nov. 23, 1920.*

The biggest consumption of crude feldspar in England is of a grade that sells in the neighborhood of £4 per ton. Ground feldspar is sold at very much higher prices, which must leave a good margin of profit to the grinder. We have succeeded in interesting all the more important grinders in the possibility of our supplying them with Canadian spar.—*From letter dated Sept. 1st, 1922.*

We are buying the pulverized Norwegian feldspar today at £11 per ton at Port. We can buy Swedish lump feldspar at about £5.10.0 per ton at the port.—*From letter dated Feb. 18th, 1921.*

We are indeed pleased to hear that there is a possibility of bringing Canadian feldspar to this country.

It was intimated to us some little time ago that we should be communicated with in reference to placing Canadian feldspar, not only in this country but abroad.—*From letter dated Nov. 23rd, 1920.*

It certainly would be useful to know that there

The Editor is apparently not familiar with the ways of the English Potter, or he would not suggest that it is quite possible that the use of Canadian spar might be a decided advantage.

was an alternative source of supply of suitable material.— *From letter dated Dec. 9th, 1920.*

A market undoubtedly exists in Great Britain for 15,000 to 25,000 tons of crude No. 2 feldspar (\$20 per ton is the price indicated).— *From letter dated July 3rd, 1922.*

While the British market may eventually be captured by Canadian spar it will take time.— *From letter dated Sept. 1st, 1922.*

The facts of the case are that Great Britain requires annually about 50,000 tons of feldspar of which 36,000 tons is supplied in the form of 60,000 tons of china stone, the remainder being imported. On its merits, Canadian feldspar is superior to any material used in Great Britain. What has chiefly militated against beginning an export trade has been prohibitory freight rates. Recently these have been so modified as to make trans-Atlantic shipments a commercial possibility.

The regrettable thing is that in the face of these facts Mr. Davis should be capable of publishing erroneous and discouraging reports.

Because the letters that I have quoted from are private, I have been unable to use the most effective paragraphs. I think, however, that I have reproduced enough to show that there is an English market for Canadian feldspar. To secure it requires enterprise and effort and the co-operation of the Government.

Toronto, Ont.

R. F. SEGSWORTH.

#### *Re. Future of Feldspar*

The Editor, Canadian Mining Journal.

Sir:— I was much surprised to note the uncomplimentary reference made by Mr. J. C. Murray towards Mines Branch officials, in his article on feldspar in the Dec. 29th issue of the *Journal*. I feel that I must go into print again in their defence, as I know they are in closer touch with all phases of the so-called feldspar situation than a number of their critics.

In Canada our chief interest is as producers, and, until such time as the consumers, particularly in the United States, are in agreement as to standards or specifications, there is nothing to be gained by the Canadian Mines Branch taking up the matter. Mr. Murray referred to the zeal shown by the U. S. Bureau of Mines in investigating conditions, but he did not intimate that the enquiry was undertaken at the request of a few consumers. The producers did not ask for it.

After a year's discussion, the matter has come down to a point where the consumers represented in the American Ceramic Society have been asked to formulate a set of standards. Individual Mills now set their own standards for buying from independent producers, and these standards are easily understood; hence, any honest, intelligent producer can control his product to a given standard, as it is simply a matter of grading as to purity, and the assistance of the Mines Branch officials should not be required.

N. B. DAVIS.

## OBITUARY

### JOHN WADDELL

On Friday, January 5th, John Waddell, associate professor of chemistry at Queen's University, Kingston, died in the Royal Victoria Hospital, Montreal, of pneumonia, contracted earlier in the same week during a holiday visit to Montreal.

Dr. Waddell was a Nova Scotian by birth, and studied at Mount Allison, in London and Edinburgh and in Heidelberg, taking degrees from all these places.

On his return to Canada he was in charge of the chemistry department of the Royal Military College, Kingston, for a number of years and then joined the chemistry staff of Queen's University, where he taught until his death. His untimely death at the comparatively early age of 62 removes one of the few remaining "old-timers" from the staff of the University.

A large circle of mining men, from Atlantic to Pacific, will long remember Dr. Waddell for the keen personal interest he took in their progress when they studied chemistry under his charge. His meticulous care and his insistence upon thoroughness have opened the eyes of many to the utility of these rare qualities. Dr. Waddell exerted to a notable extent upon his students that influence for good which is the teacher's privilege.

A widow and two daughters survive. To them the *Canadian Mining Journal* tenders its sincere sympathy.

### MANGANESE IN UNITED STATES IN 1922

Manganese ore containing 35 per cent. or more of manganese shipped from domestic mines in 1922, according to figures compiled by the United States Geological Survey from reports of producers of manganese, amounted to about 13,500 gross tons, valued at \$457,000. The ore of this grade shipped in 1921 amounted to 13,531 gross tons, valued at \$495,097. The figures for 1922 represented the actual production for 11 months plus an estimate of the production in December. More than 10,000 tons of this ore was mined in Montana.

The new tariff act, which became effective September 21, 1922, provides for a duty of \$8 a ton on ore containing 40 per cent. of manganese, \$9 a ton on ore containing 45 per cent. of manganese, \$10 a ton on ore containing 50 per cent. of manganese, and so on. Manganese should therefore bring an average price on the eastern seaboard amounting to the present average price of foreign ore plus about \$9 a ton. The new tariff has not yet greatly affected the domestic manganese market, for even under its provisions not many domestic mines can be operated at a good profit; but the owners of mines that have heretofore been worked profitably have shown a renewal of interest in the industry and some of the mines that are already developed and that yield ore of high grade will probably be reopened.

About 352,000 gross tons of ore containing 10 to 35 per cent. of manganese, valued at about \$1,232,000, was mined in 1922, as compared with 8,439 gross tons, valued at \$442,755, in 1921. About 308,000 tons of the ore of this grade shipped in 1922 was mined in Minnesota.

Up to September 21 manganese ore amounting to 266,969 gross tons, valued at \$2,324,989, had been imported into the United States in 1922, most of it from Brazil.

# Hiram Donkin

AN APPRECIATION BY AN OLD FRIEND AND CO-WORKER

After a long, active life, during which he helped to build the first Canadian railways, managed the largest collieries in Canada, and afterwards as Deputy Commissioner of Public Works and Mines planned the building of the public highways of Nova Scotia and supervised the inspection of the collieries, Hiram Donkin has retired from the Mines Department of Nova Scotia at the end of December last.

The many friends of Mr. Donkin, everywhere, are pleased to know that his faithful services to his country have been recognized and that one of the hardest working of public servants is to be allowed a breathing spell in the evening of his life. This is only as it should be. Loyalty and devotion to duty are inborn characteristics of Mr. Donkin and it is good to learn that his experience and advice are to be retained to benefit his Province. Monetary compensation for past services is meagre recognition compared to the knowledge that the youth of the present is still to have the benefit of the advice of the matured worker. In this case a fine precedent has been set.

Mr. Donkin is seventy-six and is still stalwart in appearance. Wherever he has labored, whether in the Prairie Provinces building railways, or in Nova Scotia at the collieries, he has been always held in high esteem. I first got to know him when he was General Manager of the Dominion collieries, and learned to like him, although by times our ways did not seem to run together. But, although opinions differed, yet it can be said of Mr. Donkin that he was always fair and never tried to use his position to further his own or his company's interests at the expense of others. I once overheard a group of railway men say that Hiram Donkin was a "white man," a very emphatic expression when applied to character; and while I was only a stranger among them, inwardly I heartily agreed with them.

Mr. Donkin is a big, quiet, kindly man, more fond of his home and the wild woods of his native country

We are pleased to have for publication the above appreciation of the character and public services of Mr. Hiram Donkin. Mr. Donkin has for many years discharged the duties of deputy chief of the Mines Department in Halifax, and now is superannuated, ripe in years and with an enviable record of work well done. Mr. Donkin's successor, Mr. T. J. Brown, comes likewise direct from successful management in the province's coal fields, where he has been in the mining business for over forty years, his late position being general superintendent for the Nova Scotia Steel and Coal Company. He enjoys in unusual degree the confidence and respect of the miners of Cape Breton, to whom he is intimately known, as well as the general regard of the business public of Nova Scotia. We hope that Mr. Brown will, in the midst of his principal duties hingeing on coal production, find time and energy to devote to the mining of the other minerals with which Providence has endowed his native province. —Editor, C. M. J.

than of mixing in society. In other words he is not a "club man." He has his own decided views about living, and once I heard him say that the man who did not love the forest, a pipe and a horse was not fit company for any person. Much of the life work of Mr. Donkin was spent in the great solitudes of Canada and he found that life "more sweet than that of painted pomp." He has been fond of out-door life and it has had a strong appeal to his robust, healthy nature. He has felt its call and through most of a long life, has responded to it.

MR. HIRAM DONKIN

"Now the gorges break, and the streamlets wake,  
And the sap begins to flow,  
And each green bud that stirs my blood.  
Is a summons, and I must go."

The woods is in Mr. Donkin's blood and bones, and it is a real pleasure to sit and listen as he relates his rambles through the great primeval forests, with a heart full of reverence and of the romance that fills the true lover who seeks to spend his every hour in the presence of his well beloved. Born at River Philip, in

Cumberland, Nova Scotia, he delighted in those early years "when the wintry sun the day had closed" to trail away to a neighboring farm to spend the evening with friends, and return through the great forest he loved with bounding heart and light springing foot step.

To see Mr. Donkin toiling day after day down in that subterranean little sunless office of the Mines Department and to know his love of the sunshine and of all nature, was in some measure to understand how his whole being must have continually protested against those pent-in quarters and close confinement, and how he longed for the day to come when he could bid a long good-bye and feel free to return, even for a short time, to the "trails of men."

Mr. Donkin was educated in the Great Common School of hard knocks and experience, where many others of the early Canadian pioneers had their training. Under E. H. Keating, who in after years was city engineer in succession of Halifax, Duluth and Toronto, and later in charge of the Government Railway between Truro and Pictou, Mr. Donkin worked as chainman, levelman and rodman until he was put in charge of a transit. From there he went to Northern New Brunswick, following the same line of work. He came back to work on the eastern extension of the I. C. R. between New Glasgow and the Strait of Canso. From there he went to Vermillion Bay, between Winnipeg and Lake Superior, as Government engineer on the Canadian Pacific Railway, which was then being built. After this railway had been completed to Port Arthur and taken over by the C. P. R. he went north of Lake Superior, where he became a railway contractor.

In 1885 he came back to Nova Scotia and built the eastern extension of the Intercolonial Railway from the Strait of Canso to Sydney. In 1891 this part of the road was completed, but the claims for extras were not settled, and Mr. Donkin had to spend a year in Ottawa until the claimants were satisfied. In 1893 he was appointed resident manager of the Dominion Coal Company, and put the railway through from Sydney to Louisburg.

Three years later he was appointed general manager for the Dominion Coal Company. He served five years in this important position, during which time coal mining in Cape Breton was revolutionized, mining machinery was introduced and the coal industry experienced a great expansion. In 1901 he went back with the Nova Scotia Government, and afterwards did some work for the Cumberland Coal and Railway Company, and the McKenzie & Mann, Company at Inverness; also the Nova Scotia Steel and Coal Company. In 1904 he was appointed mining engineer of the Dominion Coal Company and in 1908 was asked to accept a position in the Mines Department, Halifax, as Deputy Commissioner of Public Works and Mines. In this, as in all his other positions he was highly successful, and filled it with ability. That he may long live to enjoy the fruits of his labors, is the wish of his host of friends throughout Canada.

JOHN MOFFATT.

Preliminary returns of bituminous coal production in the United States during 1922 indicate a total of about 408,000,000 tons, which is practically the same as the 1921 production.

## THE MINES ALONG THE T. & N. O. RAILWAY

The annual report for 1921 of Mr. A. A. Cole, mining engineer to the Temiskaming and Northern Ontario Railway Commission, was issued in December last. It contains, as usual, a wealth of detailed information about the silver mines of Cobalt and the gold mines of Porcupine and Kirkland Lake. A number of the outlying non-producing gold areas are mentioned briefly, as well as the barite deposits of Elk Lake, Yarrow and Matachewan. The statistics as to production, costs, and methods at the gold and silver mines and mills, here collected in one place, form a valuable repository of precise information.

## CENTRIFUGAL PUMP

One of the new designs of centrifugal pump, as built by the Smart Turner Machine Co., Ltd., Hamilton, Ont., is shown by the accompanying illustration. The pump is of the double suction pattern, consisting of a scroll shell, with two shell sides and a Y suction pipe. The suction pipe on the pulley side is provided with a water-sealed stuffing box and a brass-lined journal to

support the end of the shaft. The shell sides may be removed for inspection of the impeller without disturbing the Y suction pipe. The impeller is of the enclosed type, is designed for the required capacity and head, and is highly finished. The pedestals are of the self-oiling type. The whole pump is liberally proportioned for hard service. It is built in sizes from two and a half to twelve inch discharge. While the illustration shows the pump for belt drive, it is also built for direct connection to electric motor, steam or gasoline engine.

The value of hydro-electric energy as conserving coal consumption in Canada may be partly gauged by the fact that only one and a half per cent. of the total coal consumption takes place in central electric power stations. In the United States 2.6 per cent. and in the United Kingdom 9.7 per cent. of the total coal consumption occurs in these stations. In 1920 over 97 per cent. of all the power output from central stations in Canada was produced from water-power. The steady growth of water-power development during the past two years indicates that this proportion will be maintained or even increased.

# Mining Industry in Alberta in 1922

By JOHN A. ALLAN\*

Mineral production during the year 1922 has been confined largely to coal. Metal mining possibilities within Alberta are relatively unimportant. Mineral development has shown signs of increased activity during the year. According to returns for 1921, Alberta ranked fourth in Canada as a mineral producer. The mineral products for that year were valued at almost twenty-nine million dollars, which represented 16.8% of the total production for Canada, and a decrease in production of 16.1 % below the previous year. The returns for 1922 are not yet complete for Alberta, but it is believed that the value of the total mineral production will be just about the same, or possibly slightly higher than in 1921 in spite of the adverse labor conditions in the form of strikes which prevented normal production from the coal mines.

## Coal

The coal mining industry in Alberta in 1922 has been struggling almost continuously with labor troubles. The mines in District 18, which includes all the districts from Drumheller and Brazeau south to the international boundary line, were closed by a strike that lasted from April 1st to August 28th — almost five months. It is estimated that this strike cost the operators approximately \$9,000,000, while the miners lost in wages about \$3,500,000.

A Conciliation Board was appointed in April, under the Lemieux Act. The report of this Board was not accepted, but an agreement between the Western Canada Coal Operators' Association and the miners was reached on August 25th, whereby work was resumed at the old rate. Since the mines resumed work, the rate of production has increased rapidly. At the end of October the output for Alberta was 300,000 tons less than on the same date the previous year. In October the output was 925,000 tons, which is the highest on record. Of this total, 250,000 tons were mined from Drumheller field. On October 16th., 304 cars were shipped from this one field.

In November an attempt was made on the part of the U. M. W. A. to organize the Edmonton field. A strike was called on December 4th. in spite of the fact that the majority of the miners were willing to work. An attempt was made to picket the miners who were willing to go to work. The situation has continued to become more serious, and many accidents have occurred to date (December 29th). Most of the mines are working, but far below capacity.

Most of the mines west of Edmonton have continued to produce throughout the year. A fire in Mountain Park Collieries in January did considerable damage. A serious fire broke out in Yellowhead Mine at Coal-spur on November 25th, and is still burning. Spontaneous combustion is stated to have been the cause. In an attempt to investigate the fire three men lost their lives on November 27th: Wm. Shaw, mine inspector; E. Roberts, mine manager; and Hiram Davis, miner,

It is estimated that the coal output for this year will be between five and one half and six million tons.

The Alberta Government has made a continuous effort to extend the use of Alberta coal on the Manitoba market through the "Coal Truth" fuel office in Winnipeg. It is stated that 65% of the coal consumed in Winnipeg this year will be the product of Alberta mines, in spite of almost prohibitive freight rates.

## Bituminous Sands

Most encouraging results have been obtained during the year from investigations carried out on the bituminous sands that are so widely distributed in the McMurray district, especially north and east. These deposits consist of loose sands more or less saturated with bitumen. The content of bitumen varies in different strata, but average material near the outcrop carries 12 to 15%. The bituminous sands are exposed along the Clearwater and Athabaska rivers and tributaries, and are known to extend over several thousand square miles, varying in thickness from a minimum where the beds have been eroded, to a maximum of possibly 300 feet, according to the latest data. The problem of extracting the bitumen from the sand has attracted much attention for the past few years not only in Alberta and other parts of Canada, but in other countries. During the summer of 1922 the first plant was erected at Waterways on the deposit, by Thomas Draper, president of the Draper Machinery Manufacturing Co., and of the McMurray Asphaltum and Oils, Ltd., both of Petrolia, Ont. The plant was completed, and a successful run was made in September. Mr. Draper expressed himself as satisfied that the process used was of commercial value. It is the intention to enlarge the plant early next spring. Much credit is due Mr. Draper for this pioneer undertaking, as it was under adverse conditions and only with the greatest difficulty that he was able to obtain ground and permission to erect this plant from the Federal Government, as the bituminous sand rights had been reserved. Furthermore, this was not a stock selling scheme, and not a dollar was asked for in this Province.

Investigations have been carried out on separation processes by Dr. K. A. Clark in the Industrial Research Department at the University of Alberta. The results to date indicate that Dr. Clark has found a practical method of extracting the bitumen from the bituminous sands. The product obtained from these deposits would be a material suitable and desirable as a surface dressing in rural road construction, and as a pavement in city streets and sidewalks. The provincial government has secured about 100 tons of bituminous sands, and has shipped them to the University. The bitumen extracted from these sands during the winter will be utilized in laying experimental road and pavement next spring. If this experiment is successful, more extended development of these enormous mineral deposits will be assured.

The Alean Oil Company has been carrying on drilling operations on the bituminous sands about forty miles north of McMurray, and five miles from the Athabaska

\* Professor of Geology, University of Alberta, Edmonton

river where the sands are exposed. At the close of the field season it was stated by those interested that a semi-fluid product had been encountered in the bituminous sandstone formation.

### *Petroleum*

The endeavour to find commercial quantities of oil in this province has been continued, with signs of increased activity.

The only production of petroleum has come from the Okotoks field or Turner Valley field, 35 miles south-west from Calgary. The production from the Royalite Company's absorption plant and the "topping plant" of the Southern Alberta Refineries, Ltd., will amount to about 10,000 barrels.

Most intense interest has been taken in the petroleum possibilities in the Sweetgrass Coumts district, close to the international boundary line, south-east from Lethbridge, as a result of the producing wells drilled ten miles south of the border in Montana in the Sunburst-Kevin field. The McLean-Mitchell well, three miles east of Coumts, is now 2,560 feet deep, and one good showing of oil has been encountered. Five other rigs have been set up in the same district, but no definite indications have yet been reported. The Imperial Oil Co. are drilling five miles west of Coumts, but have not yet reached the first oil sands. Drilling operations are also being carried on in south-eastern Alberta, north-east of Sweetgrass buttes, at Pakowki lake, and east of Medicine Hat.

In central-eastern Alberta the following companies are drilling.—

Imperial Oil Company at Misty Hills, depth about 3,300 feet; West Regent Oil & Gas Co., at Monitor, dept, 3,250 feet; British Petroleum Co., near Wainright, depth, 1,500 feet; Irma Oil Development Co., at Irma, starting to drill; Talpey Arnold Well at Birch Lake, drilling all summer;

The Imperial Oil Company have just completed the Fabyan well, east of Irma, at a depth of about 2,750 feet. The well is non-productive insofar as oil is concerned, but it has been classed as the greatest gas producer in western Canada. In April a tremendous gas flow, carrying a small quantity of oil, was encountered at 1,870 feet, estimated at 30,000,000 cubic feet per day. With difficulty the gas was shut off and drilling continued. The gas flow when the well was completed in December was reported to be from thirteen to fifteen million cubic feet per day. All these wells are situated on a major structure known as the Irma-Viking-Birch-Lake monocline. Preparations are being made for more extensive drilling operations on various parts of this structure.

South-west from Edmonton a well is being drilled at Pigeon Lake, and the Imperial Oil Company's well at Minehead on the Alberta Coal Branch, west of Edmonton, is down 1,500 feet, but no indications are yet reported.

In the Peace River district, drilling operations have been renewed on three wells. Indications of oil and strong flows of gas have been reported.

On the western boundary of the province, in the Pouce Coupé district operations on the Imperial Oil well have continued in spite of unforeseen difficulties. The well is now down about 2,570 feet and encountered showings of oil at 900 feet, and a tremendous gas flow about 1,600 feet, estimated at 30,000,000 cubic

feet per day. On December 27th an explosion occurred at the well, which injured several men. One other well has been drilled in the district, by the Pouce Coupé Oils, Ltd., to a depth of 1,500 feet before the close of the season.

In the Hay River district, south of Great Slave Lake, drilling was started last summer, but at the close of the summer the oil horizon had not been reached.

It is reported that two wells are being drilled by the Imperial Oil Company at Fort Norman. There were rumors brought out this fall that the Discovery well had a producing capacity of about 75 barrels of oil per day.

At scarcely any time during the year have there been more than twelve to fifteen drills at work. When we consider the enormous territory to be prospected by drilling between the international boundary line and Fort Norman, it is evident that there is room for increased drilling activities.

### *Natural Gas*

Considerable attention has been given to the natural gas problems in Alberta during the year. The Bow Island field, which supplies Calgary, is showing signs of decreased production.

In the Viking field, 70 miles south-east of Edmonton, there are ten gas wells with a capacity of about 32,000,000 cubic feet per day. The City of Edmonton expects to be supplied from this field. Negotiations have been completed for the purchase of this gas at a rate not to exceed 46½ cents per thousand cubic feet for domestic purposes, and 30 cents for industrial plants. It is expected that the installation of the pipe line will be commenced early in the new year.

### *Salt*

The Provincial Government drilled a well on the McMurray townsite, near the junction of the Clearwater and Athabaska rivers, in 1920, and workable beds of salt were encountered about 650 feet below the surface. Since that date the Alberta and Great Waterways railway has been extended by the Provincial Government to the Clearwater river, six miles from McMurray. In October the site for another salt well was chosen close to the railway at Waterways, and drilling commenced. If commercial beds of salt occur at this point, it is the intention of the Government to take steps to have the salt deposits developed.

### *Clay*

With the increased demand for building material, several brick plants were reopened. The Alberta Clay Products Co., and the Medalta Stoneware Limited, of Medicine Hat, were active throughout the year, utilizing clay from south-western Saskatchewan. The latter company has been enlarged and reorganized as the Medalta Potteries, Ltd. This company will manufacture white-ware in addition to the pottery products previously manufactured. A deposit of fireclay has been investigated from the Athabaska valley, 50 miles north of McMurray. Steps are being taken to develop the deposit next summer.

### *Ochre*

Ochre from a small deposit west of Banff is being utilized in the manufacture of paint by the Rocky Mountain Paint Company, recently formed in Calgary.

# Yukon Territory

## PLACER GOLD AND SILVER-LEAD

Mining in the Yukon territory has taken a decided step forward during the past year. Its production is still of course, much below that of the years of the famous Klondyke boom; but the gold dredging and hydraulic mining that succeeded the original placer digging have proceeded steadily, and the Keno Hill silver-lead deposits, which promised so well during 1921, have fulfilled part of that promise and have now, at end of 1922, ore reserves that indicate a useful future.

### *Placer Gold*

For sixteen successive seasons the Yukon Gold Company has continued its dredging and hydraulicking operations on the creeks and gulches round about Dawson. The zenith of its operations has passed; but the gold-bearing gravel still to be worked ensures continuous production for many years to come. One dredge operated on Gold Run creek during the season of 1921, and hydraulic mining in the immediate vicinity of Dawson was continued. The production from each of these operations during the season of 1921 was, in round figures, a quarter of a million dollars, and it is estimated that the season of 1922 will show about the same return.

There were five other dredges in operation during 1922 on the creeks of the Dawson area, among them those of the New North West Corporation and the allied concern, Burnall and Baird, Limited, being the most prominent. These two companies have dredges operating on Dominion Creek and in the valley of the Klondyke River.

These operations, along with a small production from scattered individual placer diggings, bring the total yield of gold for the Yukon district during 1922 to about a million dollars, the grand total to date being 210 million dollars. The dredging operations for the year have been facilitated to a notable degree by the use of water instead of steam in thawing the gravel.

### *Silver-Lead*

The Mayo silver district, north of the Stewart river, and about 150 miles easterly from Dawson, commenced its career of production in 1914, and in four years a single ore-shoot on the Silver King claim produced 2,500 tons of high-grade silver-lead ore containing about 200 oz. per ton which brought \$344,000 at prices then prevailing. In 1920 a new ore-shoot, on Keno-Hill, yielded its initial shipment. During 1921 Keno Hill, Limited, a subsidiary of the Yukon Gold Company, shipped 2,200 tons of high-grade ore, and during the past summer 3,500 tons. The ore carries about 225 ounces a ton in silver, and this gives the year's shipment a value of approximately \$750,000.

During the year a new producer has been developed, which has made a small initial shipment and promises to produce equally with Keno Hill, Limited, during the next season. This is the Treadwell Yukon Company, whose claims are likewise on Keno Hill. A number of shoots of high-grade ore have been opened up on this company's claims sufficiently to ensure a substantial tonnage for hauling over the winter roads during this winter for shipment in the spring.

The old Silver King vein has been explored further during the year, and a small shipment of high-grade ore was made last summer.

Many of the lodes of the district contain ore that has not been left by Nature in the concentrated form that is required for profitable operation. The long haul on sleighs (twenty miles or more) during the winter, the trip by barge to the Pacific and the voyage by steamer to San

Francisco or Tacoma allow of the shipment of only the richest ore. Meantime a large tonnage of milling ore is being blocked out, and the last report of Keno Hill, Limited (April, 1922) forecasted the erection of a mill. It is probable that the low-grade ore disclosed in the veins of the Treadwell Yukon Company will soon warrant a mill, and the Silver King is already known to have a considerable tonnage of milling ore.

There are a number of prospects of merit in and about Keno Hill, a number of which have been vigorously explored during the past season. None of these has as yet reached the shipping stage.

The success at Keno Hill has stimulated prospecting round about, and a number of additional silver-lead localities have been located. As yet none of these have showed ore sufficiently valuable to stand the expense of shipment. Dr. W. E. Cockfield of the Dominion Geological survey examined one such locality, Rambler, Cameron and Stand-to hills, in 1921, and his report was published last summer. The galena disclosed so far carried only about one-third the proportion of silver of the Keno hill ore, and the locality is still more difficult of access.

During the past season a considerable amount of prospecting and of development of prospects was done that has not yet been reported with sufficient accuracy to allow of any close estimate of the results attained. Meantime, it is certain that the silver-lead veins occur over a wide area and there are high hopes among workers in the Yukon about the annual production of silver they will provide eventually.

### BAUXITE IN 1922

The production of bauxite in the United States in 1922 was at least twice as large as in 1921 and may reach a total of not less than 300,000 long tons, according to James M. Hill, of the United States Geological Survey. This quantity is about half of that normally consumed, yet the increase in output is encouraging, for it reflects a larger demand by all the consuming industries, particularly the abrasives industry. The operations in the Arkansas and the eastern fields were larger, though in Arkansas car shortage in the fall limited to some extent the production.

During the first six months of 1922 the imports of bauxite averaged about 1,500 long tons a month, but since June they have been more than 3,000 tons a month. The prices of domestic dried bauxite ranged from \$6 to \$10 a ton, but were lower in the last half of the year. The prices of pulverized and dried bauxite have ranged from \$12 to \$15 a ton, and of calcined from \$20 to \$25 a ton. The effect of a shortage of coal is reflected in an increase in the price of calcined bauxite during the later part of 1922. Under the new tariff the duty on bauxite is \$1 a ton, whereas under the old tariff it was on the free list.

The calcium carbide manufacturing plant at Germiston, in the Rand, South Africa, which was built during the early stages of the war, continues to operate satisfactorily. Its output is 7 tons of carbide per day, or 2,500 tons per annum. The works are being enlarged at present.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**MINEHARING GOVERNMENT PROSPECTUS.**—Some of the statements in the Ontario Government prospectus in connection with the latest bond issue seem to indicate that officials of the Government should come under the jurisdiction of the Blue Sky law. The prospectus states that the extension of the Temiskaming & Northern Ontario Railway north from Cochrane was sure to open up a mineralized area quite of equal, if not of greater value, than that already opened up. There is, of course, no real ground for this assumption. A certain amount of prospecting has been done north of Cochrane, but, with the exception of some clay deposits, no important discoveries have been reported. The prospectus also states that it is not too much to predict that within the not distant future the gold output of Ontario will surpass even that of the Rand in South Africa. This sort of claim is what one might expect in wild-cat mining promotions, and not in a prospectus issued by the Government in connection with an important bond issue.

**THE DIABASE-KEEWATIN CONTACT AT COBALT.**—Public interest is now confined very largely to the gold fields, and very little is heard of the special work being carried on in the Cobalt camp, which may have an important bearing on its future production. During the past few years, and particularly since Mr. C. W. Knight completed his geological survey of the Cobalt area much attention has been paid to the lower diabase-Keewatin contact. The shaft of the Continental company is down over 650 feet, and should reach the contact at approximately 900 feet, when it is expected that the continuation of the main O'Brien vein will be found. On the Violet property of La Rose, which adjoins the Colonial, a great deal of work has been done on the lower contact, and some very favorable results obtained. The new shaft is being sunk to a depth of approximately 600 feet, and it is expected that the property will be producing again by next May. The Coniagas is developing the Ruby property in the Green-Meehan section, and has sunk a shaft 150 feet deep to explore the conglomerate and slates underlying the diabase. A station is now being cut and lateral work will be started immediately. The Mining Corporation has started the unwatering of the Seneca-Superior property on Peterson Lake. In the early history of the Peterson Lake the property was divided into a number of leases the Seneca-Superior being the most important, with a production of over 5,000,000 ounces. The Peterson Lake was recently taken, under lease, by the Mining Corporation, and there is a considerable area yet to explore. The Nipissing shaft No. 26 will also be explored on the diabase-Keewatin contact. No. 26 vein was worked in the early days of the camp and had a very substantial production, and it is expected that a considerable tonnage of mill rock, at least, will be encountered. The Oxford, Victory and Genessee are also carrying on new work with fair prospects of success. The Coniagas has also taken a lease on the Beaver

property, which has a shaft down to a depth of 1,400 feet, and will explore the lower contact at a depth of approximately 1,200 feet. A short distance below this point a large vein, carrying some silver, was encountered, and it is believed that the geological conditions indicate important possibilities.

In South Lorrain the Keeley property and the Frontier property of the Mining Corporation have developed into very substantial producers and extremely high-grade ore is being mined. In some places widths of 12 to 18 inches of some of the highest grade ore ever found in the district have been met with. It is expected that during the coming summer a great deal of work will be done in South Lorrain as a result of the developments at the Keeley and Frontier.

**KEELEY SILVER RESERVES.**—The recent report of the Huronian Belt Company, which has a large interest in the Keeley, states that at October 31st last, reserves at the Keeley were 1,153,300 ounces, and 324,000 lbs. of Cobalt. A new company, known as the Keeley Silver Mines Limited, has been formed, with an Ontario charter, and a capitalization of 2,000,000 shares of \$1.00 par, of which 1,343,300 will be issued. Mr. Hamilton B. Wills is President. 1922 production from the Keeley, during the first 11 months, was 687,500 ounces. It still maintains a high rate of production, and information available bears out the assumption that the company will produce approximately 1,000,000 ounces during the year 1923. During the month of November production amounted to 84,742 ounces, notwithstanding that breakages in the mill necessitated a shut down for 10 days. A new vein has been found which shows 7 inches of 1,100-ounce ore, and on the 6th level the "N" shoot on the Woods vein has been opened up for 130 feet, and averages 370 ounces over a width of 19 inches. On the 7th level the same ore shoot has been drifted on for 85 feet, where it shows 360 ounces over 18 inches. The Mining Corporation has also opened up an ore shoot, extremely rich, on this same vein, not far from the Keeley boundary.

**COBALT.**—During the year ending October 31st last, the Coniagas produced 1,158,900 ounces, which is a decrease of approximately 150,000 ounces compared with the previous year. The grade of the ore was 9.19 ounces per ton, compared with 10.7 ounces per ton in the preceding year. The cost of mining and concentrating was 32.6 cents per ounce, and the average price received for silver was 70.8 cents. Profits amounted to \$369,000, and \$200,000 was paid in dividends. During the year the company spent \$54,000 examining properties, which includes \$18,000 spent in diamond drilling the Newray. At the present time options are held on properties in Coleman, Tisdade & Buckle Townships, the option on the claims in McVittie having been allowed to lapse. The Coniagas has also taken a lease on the Beaver, Prince, Davis and Badger properties. It is understood that work at the Beaver will be started as soon as a pre-heater for air is obtained for the hoist.

October production of the Mining Corporation was 124,811 ounces from 5,527 tons of ore, as compared with

production of 173,000 ounces in September. During October, however, operations were suspended for 11½ days, on account of the fire. A large part of the production is now being obtained from South Lorrain and the company has started to haul ore with its tractor.

The Nipissing Extension Mines Company, which owns the old Farrah property, now under lease to the Mining Corporation, is apparently attempting the methods of some of the recent wild-cat flotations, and is offering what are called "subscription rights." As is usual with this class of promotion, facts are misstated and prospective investors are lead to believe that the Mining Corporation is developing valuable ore, and that a substantial production is assured. The Mining Corporation has informed the newspapers that these statements were made without their knowledge or authority and that the company is not interested in any way in the sale of these "subscription rights." It is understood that there is a small surface showing of silver on the property, but that the underground work done by the Corporation has not yet succeeded in finding any ore. The company has a lease on the property for five years, on a royalty basis of 15 per cent. on the net smelter returns. During the life of the lease the company has to spend \$1,000 a month.

**PORCUPINE.**—The power situation in Porcupine is still unsettled, but officials of the Northern Canada Power Company announce that 4,000 additional h.p. will be available from the Sandy Falls plant before the end of January. This will be distributed among the McIntyre, Dome and Hollinger, and it is not believed that there will be any power immediately available for other properties. In the meantime the Rochester is installing a fuel burning plant, and the West Dome Lake and the Clifton are operating on steam.

The West Dome Lake will be unwatered in the near future, and underground operations will be started immediately.

Clifton officials advise the shareholders that the inability to secure electric power is a very severe handicap. The steam plant is of small capacity and the new mill is being operated in only a small way, and is used very largely as a means of sampling veins over stopping widths. It is also stated that the pool existing in the stock will end December 31st, and shareholders are advised against any hasty attempt to sell.

The Dome Mines will ask for a Dominion Charter to permit carrying out the re-organization plan whereby 4 shares of no par value will be given for each share in the present company. Developments at the mine continue to be satisfactory and production is being maintained at approximately \$350,000 a month.

The McIntyre is treating close to 800 tons a day and the average grade of the ore is approximately \$11.00 per ton. Developments at the property continue to be very satisfactory, and it is expected that the output in the near future will exceed that of the Dome.

Preparations are now under way to start clearing a right-of-way for the transmission line from the plant of the Great Northern Power Company at Matachewan to Night Hawk Lake and Porcupine districts, and one hundred men will be engaged for this purpose. The Ontario Government has a force of men engaged in building a road from Elk Lake to Indian Chutes and

Matachewan, over which it is expected a great deal of mining machinery will be hauled this winter. As soon as hydro-electric power is available, it is understood that work will be started in Matchewan on some of the properties that have been closed down for some time. The Matchewan Gold Mines, which has a substantial amount of ore running in the neighborhood of \$11.00 per ton, will undertake a considerable amount of underground development in order to get ready for a mill.

**KIRKLAND.**—The Lake Shore is making preparations for extensive additions to the plant and mill. New buildings are being put up and a new compressor has been installed and a new hoist ordered. It has also been decided to install a 75-foot steel head-frame and a crushing plant at the shaft. The crushing will follow the lines of the Hollinger and will consist of crushers and rolls, and will have a capacity of over 500 tons a day. Additions will be made to the precipitation end of the mill, which will permit the precipitating of \$6,000 per day. Assuming the ore to average \$20.00, this would mean mill capacity of approximately 300 tons a day.

It is understood that the December production of the Teck Hughes was over \$100,000. It has apparently been decided to run low-grade and high-grade ore through the mill on alternate months, as it is found that the high-grade ore takes a very much longer treatment.

The Continental has started sinking on the Post claims, which it has under option. An electrically driven mining plant will be installed, and surveys are now being made for the transmission line. The company recently reported that it had uncovered on the surface a vein for a length of 100 feet, which averaged \$8.00 over a width of 5 feet. A shaft has been commenced on this vein.

The Montreal-Ontario, in an official statement, advises that a porphyry dyke, averaging \$10.00 has been cut, and that recent developments underground have given encouraging indications.

The Lebel Lode is making preparations to install a mining plant. A general meeting of the shareholders has been called to ratify a by-law authorizing the directors to sell 1,000,000 shares of treasury stock at a discount.

The Crystal Lake Gold Mines will install a mining plant this year and if financial arrangements permit will sink a shaft to a dept of 500 feet.

It is understood that the newly formed Swastika Gold Mines plans to do a considerable amount of diamond drilling on its properties in the Kirkland district.

Better results are now being obtained at the Kirkland Lake Proprietary mill, which is treating ore from the Tough-Oakes and Burnside properties. During the month of November \$24,000 was recovered from 2,000 tons, which is the best grade for some years. The capacity of the mill is about 120 tons a day, and an endeavor will be made to increase the tonnage. The company made a profit during November on the higher grade ore, as a result of recent developments on the Burnside properties.

The Lake Shore output for November was \$32,746, from 1912 tons, or an average of \$17.10 a ton, which is the highest production of any month since last July. With the enlargement of the shaft completed, mining operations are back to normal, and work is being car-

work on at several different faces. Preparations are being made to sink the shaft to 800 feet, work on which will be started immediately.

Monthly outputs from the Teck Hughes have shown a great variation during the last few months. In September the production amounted to \$118,000, which is a record in the history of the company. The property was shut down in October, through shortage of power due to the fire, and in November production dropped to \$40,000. It is understood that the December output will be high as compared with that of November.

**SILVER TAIL.**—It is reported that on the Herriek property, in West Shining Tree, which is under option to the Tonopah Mining Company, the crosscut at the 300-foot level has encountered 14 feet of ore, which shows visible gold.

**NEWFOUNDLAND.**—Two companies have already been formed to take over claims on Big Brook, near Stag Harbor on the Labrador coast, where placer gold is reported to have been found last fall. The Labrador Gold Fields Limited has been formed, with a capital of \$50,000, to take over 80 claims. It is expected that the capital will be subsequently increased. It is the intention of this company to divide the ground up into small parcels and lease, as it is believed that the ground is rich enough to permit of the old fashioned methods of cradle and rocker. In St. Johns, Newfoundland, the Stag Gold Mines Limited has been formed with a capital of \$5,000,000, and this company will also control a large number of claims. Stag Harbor is about 630 miles from St. Johns, Newfoundland, and the reported discoveries are on Big Brook, about 25 miles inland. So far, very little is known of the district, and it is too early to express an opinion of its possibilities.

## BRITISH COLUMBIA

**THE ENGINEER SHOWING.**—Reports persist that the Engineer Mine, Atlin, is to be acquired by eastern mining investors. If this British Columbia property is taken hold of and seriously developed it may possibly fulfil the promise of its bonanza outcrop. If it should develop into a genuine producer it will constitute another important advance in the development of the mineralized zone known as the "eastern contact belt," which extends northerly from a point below Alice Arm, through the Salmon River valley, to a point north of the Engineer. A ready within this territory there are four well known mines, viz., the Dolly Varden, the Hidden Creek Mine (Granby Consolidated Mining & Smelting Co.), the Premier and the Engineer. Of the last it is interesting to quote the Minister of Mines Report for the year 1918: "Altogether it is a wonderful showing of gold and there is every reason to believe that it can be developed into one of the greatest gold producers of the continent. Development consists of a number of open cuts, and in the neighborhood of 1,000 feet of underground work, exposing some 25 veins varying in width from a few inches to 4 feet, the majority showing visible gold. All this underground work has been in ore. A ball mill was erected on the property by the late Captain Alexander. The record run of this mill was 24 lbs. 8 ozs. (Troy) of gold from 160 pounds of ore."

**DRUM LUMMON.**—A considerable amount of work has been done in recent months on the Drum Lummon Mine,

Douglas Channel. A shaft is being sunk to develop the ore-body at 100 feet below the main level and a new ore-body has been proved up east of the present cross-cut tunnel. An assay return from the same is given as follows: Gold, 0.01 oz.; silver 7.5 oz.; copper, 19.5 per cent. A dock has been built at tidewater and new machinery is being installed. A semi-Deisel engine will supply motive power and compressed air will be supplied by a Laidlaw compressor of 500 cu. ft. capacity. It is reported that a campaign of diamond drilling will be started as soon as conditions permit. Glenville Collins, engineer in charge, expects to be able to make some shipment to the Granby Smelter shortly.

**DOLLY VARDEN.**—The Dolly Varden Mine, Alice Arm, is to be taken over by George Wingfield, of Nevada, who advanced \$182,322 in 1921 to the Taylor Engineering Co. on the security of their holdings at Alice Arm. These financial obligations have not been discharged and Mr. Wingfield is taking the necessary steps to secure control. What his plans are as to the property, has not been announced, but it is hoped that the new owner will develop the mine and operate the eighteen miles of railway from tidewater to the workings on the Kitsault River. The railway serves, besides the Dolly Varden Mine, a number of gold prospects so that prospectors and miners of the district are keenly interested in the matter. It has been suggested that Mr. Wingfield might seek to dispose of the entire property, which includes modern mining machinery at the mine, a short tramline and bunkers at the railhead, the railway referred to, and bunkers at the beach. The railroad cost roughly \$1,000,000 to build. It was completed in 1920 and operated that season, bringing a considerable quantity of high-grade ore from the Dolly Varden to Alice Arm. Since then it has been idle. Mining men, however, believe that prudent development will put the mine in shape for shipping and that the Wolf group of claims, which are adjacent, are of sufficient promise to merit more attention.

**TRAIL SMELTER RECEIPTS.**—The Trail Smelter, Canadian Consolidated Mining & Smelting Co., received 4,923 tons of ore during the week ending December 14th last, of which 4,657 tons came from the company mines. In addition there was a shipment of 170 tons from the Silversmith, Sandon, and one of 52 tons from the Surprise, Republic. For the week ending December 24th ore receipts totalled 7,631 tons. Among the independent shippers were the Alamo Alamo, 90 tons; Black Rock, Northport Wn., 125; Galena Farm, 12; Knob Hill, Republic, 103; Northport Smelter, 346; Paradise, Windermere, 42; Quilp, Republic, 52; Ruth, Sandon, 34; Silversmith, Sandon, 122; while the company mines contributed 6,653.

**DISPUTED CLAIMS.**—A writ has been issued on behalf of the Silver Ores Inc. against the Premier Gold Mining Company of British Columbia, the purpose of which is to "recover title to certain Salmon River mineral claims known as the Premier Extension Nos. 1, 2, 3 and 4, the Extension Fraction, the True Blue, and the Gloria Fraction." Counsel further explains that "it will be alleged that Captain Fader, then president of Silver Ores Inc. purchased these claims with the funds of the Silver Ores, took the deeds in its own name and fraudulently sold them to the Premier Gold Mining Co., whose property immediately adjoins the Premier Mine."

R. F. Ainslie, of Syracuse, N. Y., is reported to have bonded the Galena Farm Mine at Silverton, on which property development has been resumed.

**BRITANNIA.**—Latest information from Britannia Beach is that the Britannia Mining & Smelting Company expects to be in a position to start shipping in February. Mill construction and machinery installation now are well advanced and the Victoria Mine, recently opened, is in condition to commence feeding the mill as soon as it is ready. About 750 men now are employed in the mine and at the works. With the resumption of active productive mining operations there will be about 1,000 men continuously on the pay roll.

**COAL MINERS' CERTIFICATES.**—Twenty candidates sat for examinations conducted recently at Nanaimo, Fernie, Merritt, and Cumberland by the Board of Examiners, appointment under the "Coal Mines Regulation Act." They wrote for first, second and third class certificates, although the majority took the papers of the last two classes. Of the twenty who offered, ten were successful and the Board, in its report, observes that "most of the candidates for Second Class, and a few of those for Third Class certificates, possessed a knowledge of mining matters and gave proof of a general education considerably above those usually manifested by aspirants for these certificates."

A list of those successful follows:

Second Class: Robert Kelly Smart, Nanaimo; Daniel Walter Thomas, Cumberland; William Archibald, Merritt; Frank Yates, Michel.

Third Class: James Bainbridge, Nanaimo; Thomas Claud Vincent, Coalmont; George Carroll, Nanaimo; William Weaver, Michel; Robert Winstanely, Michel; James Phillips, Nanaimo.

**ASSAYERS' CERTIFICATES.**—An Assayer's examination of candidates for Certificates of Efficiency under the "Bureau of Mines Act" was held last week; William Fleet Robertson, the Provincial Mineralogist being the Chief of the Board of Examiners. There were three candidates and all were successful as follows: G. W. Cotton, Kurt Raht, L. H. Wenerstrom.

It is a matter of comment that Messrs. Cotton and Raht of the Trail Smelter both obtained 91 per cent of the possible marks, a record only once exceeded since the establishment of examinations in this Province.

### CARIBOO, B. C.

Though the gold production of the Barkerville district during the season of 1922 was disappointing, due to the dry season, an important amount of exploratory work was done, which provide bright prospects for 1923.

Keystone drilling has disclosed payable placer ground on Swift Creek, under lease to Detroit investors represented by Messrs. Kerr and Dunlop, and it is intended to install a dredge shortly. Drilling has also established paying dredging values in the old bed of Williams Creek, Grouse Creek and Antler Creek, which await capital for development.

During 1922 some promising discoveries were made by individual prospectors. Leopold Muller ran a 600-foot tunnel on Dragon Creek, where he disclosed good values on bed-rock, the gold being coarse and about 900 fine. This ground is capable of being hydraulicked.

Houser brothers struck some very good pay in the Devil's Canyon, where they operated a small hydraulic

plant. John MacDougall has a gang of men drifting on Jack o'Clubs Creek, where the present values average \$4.02 per 10-foot cap. F. J. Tregillas, Jos. House and F. Reed are preparing to open up their property on Cunningham Creek, where they expect to have a successful season next year, all the factors for cheap hydraulic mining being favorable.

The strike at Cedar Creek has stimulated prospecting on the higher benches, and it is expected that this will continue during the coming season.

The work last summer of Dr. W. L. Uglow for the Geological Survey at Ottawa has drawn attention to the quartz showings of the district. On Proserpine Mountain some rich ore has already been found. Mr. Cleaves, representing eastern capital, has a few men working on quartz showings on Lowhie Mountain and at Red Gulch on Mosquito Creek. At the former place he is driving a tunnel to intersect a vein on the Rainbow claims, where Mr. Sanders found some spectacular ore last summer. Mr. Ernest Moore found several promising quartz veins last season on upper Cunningham Creek, and Mr. Wells, of Seattle, is preparing to explore them systematically next spring.

Practical researches into the use of drills and drill steel in the Rand mines recently have already resulted in economies. Steel is now more uniformly gauged and tempered and the drills are inspected and overhauled systematically.

It is proposed to install at the Modder Deep on the Rand, a flotation plant to separate pyritic material from the sand before leaching. Experiments indicate that the separate treatment of this pyritic material will prove to be profitable.

There are now a large number of trade associations in the United States at work on co-operative industrial research. *Industrial and Engineering Chemistry* gives a partial list of these showing 42 trade associations.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch) \$2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclose ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

**WANTED**—Safety Engineer for Canadian Gold Mine. Applicant must have had previous experience in the work. Diplomacy in dealing with staff absolutely essential. Salary \$250. per month to suitable man. Box 545 Canadian Mining Journal, Gardenvale, Que.

## ANNOUNCEMENT

### CHANGE OF CORPORATE TITLE

SINCE MR. HAMILTON B. WILLS HAS NOT BEEN ACTIVELY CONNECTED WITH THE AFFAIRS OF HAMILTON B. WILLS & CO., LIMITED, SINCE JULY, 1920, AND HAS HAD NO CONNECTION WHATEVER FOR OVER A YEAR, IT HAS BEEN DEEMED ADVISABLE TO CHANGE THE NAME OF THE COMPANY TO REFLECT THE MANAGEMENT SELECTED BY MR. WILLS TO SUCCEED HIMSELF.

THE CHANGE OF NAME IS A FORMALITY AND DOES NOT AFFECT THE AFFAIRS OF THE COMPANY IN ANY WAY, SHAPE OR MANNER.

**ARTHUR E. MOYSEY & CO., LIMITED**  
FORMERLY KNOWN AS  
**HAMILTON B. WILLS & CO., LIMITED**

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machine or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

- |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars** relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**
- Summary Report.** The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memoir 108. The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, tale and zinc. This Province has the largest deposits on the continent of tale, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.         | Value.      | Year.         | Value.       |
|---------------|-------------|---------------|--------------|
| 1891 .. . . . | \$4,705,672 | 1906 .. . . . | \$22,388,383 |
| 1896 .. . . . | 5,235,003   | 1911 .. . . . | 41,976,797   |
| 1901 .. . . . | 11,831,086  | 1916 .. . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## The British Empire Steel Corporation, Limited

by reason of the magnitude of the operations  
of its constituent companies, is able to render  
a wholly unique service to the industrial or-  
ganizations of the world—and of Canada in  
particular.

The vast scope of these operations necessitates  
the maintenance of the highest possible stan-  
dards of efficiency and economy, which,  
naturally, reacts to the benefit of our cus-  
tomers.

MONTREAL, CANADA

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his claim, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, \$76,177,403; Lode Gold, \$105,557,977; Silver, \$55,259,485; Lead, \$18,330,575; Copper, \$166,393,488; Zinc, \$21,848,531; Coal and Coke, \$225,409,505; Building Stone, Brick Cement, etc., \$34,072,016; Miscellaneous Minerals, \$1,210,639; Making its mineral production to the end of 1920 show an

**Aggregate Value of \$734,259,619**

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for the year 1916, \$42,290,462; for the year 1917, \$37,010,392; for the year 1918, \$41,782,474; for the year 1919, \$33,290,313; 1920, \$35,543,084; 1921, \$28,066,641.

**Production During last ten years, \$336,562,897**

Lode mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

## -:- EDITORIAL -:-

*Your operations and influence cover the whole of this wide Dominion, ... representing in a very comprehensive, in the most far-reaching manner, the interests of the country at large. — Lord Aberdeen (to the Federated Canadian Mining Institute) — 1897.*

### AN INSTITUTE FOR TECHNICAL EMPLOYEES

Seven weeks from now the Annual Meeting of the Canadian Institute of Mining and Metallurgy will be in session in Montreal. A technical program of first-rate interest has been prepared, and a number of questions of prime importance will be discussed. It is well that important points should be brought to the notice of the Institute's members beforehand in order that the discussion at the meeting may be fully beneficial and a snap judgment on important points avoided. The *Monthly Bulletin* of the Institute and the *Canadian Mining Journal* are the principal agencies to this end.

Last week we pointed out a very serious danger to which the Institute has been subjected by action of Council — a danger that will strike at the heart of the Institute's independence unless prompt action is taken to avert it. Today we wish to discuss briefly a matter that has already been put before all the members, though the lack of general discussion of the point, apart from those primarily responsible for the move, tends to show that few realize its import.

A circular, dated November 30th, has been sent to all members notifying them of a motion to amend section 58 of the by-laws thus:

1. Members shall not be less than twenty-seven years of age and shall have been for at least five years in responsible positions with regard to practical mining and metallurgical work; or shall be such other persons as shall be otherwise eligible in the opinion of the Council by reason of their scientific attainments or technical knowledge; or shall be enrolled already in the Professional Membership class, or Membership class of the Institute at the time that this Amendment comes into force.

2. Associates shall be persons engaged in practical mining and metallurgical pursuits and shall have been so engaged for a period of three years at least, and such other persons as the Council may decide to be eligible through connection with mining affairs; or shall be enrolled already in the Associate Membership Class of the Institute at the time that this Amendment comes into force. Associate members shall be entitled to vote, but may not hold office.

3. Students shall be persons not under eighteen years of age and not over twenty-five years of age, who intend to adopt the profession of a mining or metallurgical engineer; or, shall be already a student member of the Institute at the time this Amendment comes into force.

The import of this motion is virtually that memberships in the Institute shall be confined to technically trained engineers, metallurgists and geologists and those whose practical experience has given them a

similar qualification. It would exclude all others, whatever their interests in the Institute or in the mining industry — these latter being represented at present by almost half the total membership.

This policy of an Institute that is practically a closed corporation, open only to the technical employees of the mining industry, has been openly and vigorously advocated for some time past by a number of the members, particularly those from British Columbia. There is a real need for a closed technical organization, and as we have pointed out in these columns, that exclusively technical membership already exists in the Professional Members of the Institute, though the active organization is still lacking. We believe that by supplying life and activity to this inert corpus, all the principal objects of the movers of this amendment can be accomplished.

The spirit of this amendment is, we believe, in direct opposition to the spirit of the men who founded the Institute twenty-five years ago — a spirit that we are confident still animates a large majority of the Institute's members, professional and otherwise. The spirit of service to the industry is vastly superior to the spirit of service to a limited class of employees of the industry, however pure may be the motives of these employees and however solicitous their care for the industry's welfare. It is well to remember that the mining industry has got along before this, and could exist again, without the aid of technically trained engineers, whereas these engineers are wholly dependent upon the industry for their technical existence. A purely technical Institute might conceivably be of great benefit to the industry; but selfish human nature being what it is, we much prefer to see the industry guided and watched over by an Institute more nearly representative of all its interests.

We must not be frightened by our Secretary's cry for an "open door" to membership. Mr. Mackenzie knows well that a good argument is the best means to create a live interest in Institute affairs. He intends no more than the rest of us to flood the Institute with undesirables. The fact is that at present there is nothing in the by-laws, nor has there ever been, to exclude the "mob"; yet the "mob" has not been admitted, nor will it be so long as the Institute preserves its present high ideals of independence and of service to the mining industry.

## LABRADOR

On two occasions during recent months the *Canadian Mining Journal* has published articles dealing with the possibility of mineral development in Labrador, with a view to stimulating interest in that little-known part of our continent. Dr. Kindle's brief account of his journeyings there during the summer of 1921 on behalf of the Geological Survey and the Department of Justice is full of hope for the future mineral production of that unexplored land — as large as *Alaska* and less known to us than any other part of the continent. Mr. William Agar's trip along the coast with Dr. Grenfell during the same summer gave him an opportunity to study the rocks in numerous places, and his impression, too, is to the effect that the rocks and their geological associations offer great promise to the prospector.

Dr. Kindle mentions gold thus: "Placer gold of commercial value may never be found in Labrador, but if it should be found in the sand and gravel terraces which run inland for hundreds of miles along the lakes and rivers west of Hamilton Inlet, the water supply furnished by hanging valleys would afford numerous opportunities for hydraulicking on a mammoth scale." Unfortunately, these same hanging valleys are an evidence of recent glaciation, and it is this glaciation that has scoured the placer deposits from off the major part of Canada. However, Mr. Agar gives us some hope for the existence of placers when he reports that the higher levels of northern Labrador are unglaciated, having remained above the sea of ice that covered the lower levels. Likewise there is always the possibility of the glaciers having over-ridden small areas, possibly gold-bearing, when they swept bare the surrounding hills and valleys.

The public have been invited recently to put their money into a venture for placer mining in Labrador. It is quite possible that there may be payable placers in Labrador, and in the locality specified. The terms in which the alleged placer deposit is described are, however, so ridiculous that they demonstrate quite conclusively that the writer of the advertisement either does not know what he is writing about, or that if he does, he has intent to deceive the reader. Even granted that the incidents relative to the discovery of gold and the assay values are exactly as described, the deductions from these data are absurd. From the ridiculous nature of the deductions, we would judge that the statements of alleged fact should be subjected to very close scrutiny before acceptance. If there were associated with the enterprise experienced mining men, or if there were evidence that a reputable and qualified mining man had been consulted while this *venture* has been formulated, we would be much better satisfied of the "bona fides" of the promoters.

We hope sincerely that a genuine discovery of placer

gold in paying quantities will be made in Labrador. The land is relatively easy of access, and the profits from placer diggings would thus be large. No other mineral discovery would attract men and capital so quickly or so surely; nothing else would give so strong an impetus to the exploration of that vast and desolate "land that God gave to Cain."

## BANKERS AND MINERS

A pronouncement of first-rate importance to the mining industry is that made by Sir Edmund Walker recently in his address to the share-holders of the Canadian Bank of Commerce at the annual meeting. This is one of the few instances within recent years where a Canadian in a position of the highest financial responsibility has been able to gauge Canada's mining industry at its true value, and has dared to express his conclusion in unequivocal terms. Few bankers realize, even now, that mining in this country is now an industry, directed and controlled, in the main, by well-qualified engineers and responsible executives. Few Canadians have a clear vision, such as that now exemplified by Sir Edmund Walker, of the place mining is destined to take in Canada's economic organization.

It was expressly with the object of stimulating thought in the minds of men of wide experience and capable of independent and well-founded judgment that Dr. Corless made his startling pronouncement before the Canadian Institute of Mining and Metallurgy now almost a year ago. Sir Edmund Walker has been the first, outside the mining profession, to respond publicly. His position of leadership in financial circles in this country will ensure that others will follow him in exploring the possibilities of the mining industry. We of the mining profession must make sure that wise guidance is provided for these strangers during their initial excursions into the mining field, if we are to reap the full benefit of their co-operation.

## A PRACTICAL SUGGESTION

When the personnel of the Hon. Harry Mills' Iron Ore Committee was announced some months ago, it was at once obvious that its function was to examine in a general way the conditions surrounding the possible production of iron ore in Ontario, and to advise a suitable course of action. As none of the members of this committee have, heretofore, studied the iron ore business in a comprehensive and thorough way, their conclusions must, of necessity, rest upon evidence adduced by, and ideas provided by, men who have made iron ore a special study and whose record shows a capacity for sound judgment and shrewd conjecture.

Messrs. A. Hasselbring and G. W. McLeod have written the article we print today with the express object of creating discussion along the line that they consider will be most fruitful of practical result. Mr.

Hasselbring is one of the very few mining engineers in Canada who can speak with authority and from personal experience about iron ore mining in this country. He has mined a large part of the iron ore produced in Ontario, and was instrumental in developing to the point of technical success the beneficiation process that has come closest to commercial success—that at Magpie Mine.

We recommend for the closest attention of any interested in a Canadian iron ore industry the suggestions made by Messrs. Hasselbring and McLeod.

### EDITORIAL NOTES

We are pleased to welcome back to our pages today Mr. Alexander Gray. Mr. Gray was seriously ill during December last, but is now, happily, well on the road to recovery. We have had numerous inquiries from readers who have missed his searching comments and pithy news items during the last six weeks.

Tear off the front cover of today's *Journal* and post it on your notice-board or in the dry or shaft-house. If you wish to have extra copies, a request to the editor will bring them.

Lately there have been a number of wild-cat mine promotions "wished on" honest prospectors and operators by promoters whose zeal has outstripped their discretion and sense of common honesty. Today we print a letter from a prospector, Mr. Robert Holding, in which he publicly disavours any connection with "Holding Consolidated Company, Limited," who have used his name without his consent and of whose stock-selling methods he emphatically disapproves. Public statement of facts such as these might do much to alleviate the stock-jobbing evil.

It is an unquestionable fact that mining men in general are "dead set" against fraudulent mining schemes. More often than not, however, this conviction begins and ends with a pious expression of personal opinion. It is encouraging, therefore, to find the commencement of an organized effort among mining men to expose and suppress fake schemes. The members of the National Shale Oil Conference, at the American Mining Congress in Cleveland last October, passed the following resolution: "That every member...be urged to use his every effort, individually and collectively, to prevent the promotion of fake oil schemes..." Practical means designed to be effective, were adopted to put this resolution into effect. Members of the Canadian Institute of Mining and Metallurgy — take notice, please!

If there remain in Canada any persons capable of thought and deduction who still hold to insular ideas and who still are ready to deny the fact of the world's commercial unity in these modern times, the events

of the last few days must have gone far to convert their views. The virtual cessation of mining in the iron ore mines of the British Empire Steel Corporation at Wabana, Newfoundland, consequent upon the military occupation of that part of Germany to which this ore has been shipped in such large quantities recently, will bring home to Newfoundlanders, if not to Canadians, in a very personal way their interest in events in Europe. The increase, on the other hand, of British coal exports consequent upon Germany's necessity for finding an alternative source of supply, will give to the British people a decidedly heightened interest in the preservation of Germany as a political entity and her speedy commercial rehabilitation.

### HISTORY

I

When men first started mining.  
One prehistoric day,  
No doubt there was repining  
About the rates of pay.

\* \* \*

I fancy then they tore rocks  
With elemental fire,  
And, doubtless, used the aurochs  
(Our cattle's pristine sire)  
To do the heavy hauling  
Of timber and of ore;  
He'd take a load appalling,  
That animal of yore.  
I fancy that the pay-roll  
Was totted up in runes:  
He must have had a gay role  
Who paid off those poor prunes  
For then there was no specie;  
(Pray bear that fact in mind).  
The workers, stark and greasy,  
All took their pay in kind.  
So when a worker wanted  
To get his pay in wife,  
How sorely he was taunted,  
How wretched was his life,  
When pay-day brought him merely  
A fig leaf or a skin!  
He must have cussed sincerely  
The chap who took him in!

\* \* \*

When men first started mining,  
One prehistoric day,  
No doubt there was repining  
About the rates of pay.

# An Iron Ore Industry for Ontario

A PRACTICAL PROPOSAL FROM TWO  
MINING ENGINEERS

By A. HASSELBRING AND GEO. W. McLEOD

As a result of the investigation being carried on by the recently appointed Ontario Iron Ore Committee, we here offer some suggestions and remarks that we hope will be useful to the Committee and that we also hope will cause some helpful discussion among those throughout the Province who are interested in the iron ore question.

There are in Ontario many deposits of iron ore, all of which fall under three main heads, i.e. Magnetite, Hematite and Siderite. These classes may again be subdivided into numerous groups.

## Magnetite

Under Magnetite we have in Ontario three main subdivisions.

1. *Low-grade magnetite.* The low-grade magnetite must again be sub-divided into two classes, A.—Those deposits that consist of alternate bands of fairly high-grade ore and silica. (The Big Dave Property in the Michipicoten area is an example of this type of deposit.) B.—Those deposits that are uniform throughout in their composition, the silica being intimately mixed with the magnetite. (Examples of this type are the Goulais River deposits and the larger part of the Moose Mountain deposit.)
2. *Good grade magnetite with high sulphur content.* An example of this type is the deposit at Atikokan Mine.
3. *Titaniferous Magnetite*, extensive deposits of which occur in the Rainy River District as well as at other places throughout the Province.

## Hematite

1. *Low-grade, high silica hematite* fairly uniform in character; examples of this are found in the deposits in the vicinity of Lake Nipigon.
2. *Low-grade banded deposits*, where some of the bands consist of a fair grade of ore. A deposit of this type is found in the vicinity of Loon Lake, 26 miles east of Port Arthur.

The only known body of high-grade hematite of any considerable size is located at the Josephine Mine in the Michipicoten District. This body contains less than a million tons of recoverable ore.

The Helen hematite deposit has been worked out.

## Siderite

This ore may be classed under two headings; high sulphur siderite and low sulphur siderite.

An example of the first type is the Helen siderite deposit and an example of the second type is the Magpie Mine deposit.

## Large Known Ore-Bodies

There are in Ontario several ore-bodies with large known tonnages that come under the types mentioned above. Some of these ore-bodies have been proven by diamond drilling and by exploration work while natural exposures on others show that they contain immense tonnages.

Among the most conspicuous of the proven ore bodies are the Helen high sulphur siderite, the Moose Mountain low-grade magnetite and the Atikokan high sulphur magnetite. The most prominent of the naturally exposed ore-bodies are those near the Goulais River, which consist of a low-grade magnetite uniform in texture.

## The Problem

We have given an outline of the different types of ore-bodies that exist throughout Ontario to show that totally different treatment is necessary for the beneficiation of each individual type of deposit. No two of the types of deposits mentioned above are amenable to the same treatment. For some types the treatment may be the same up to a certain stage, but the final stages will be radically different for each type, so that the beneficiation of each type is a separate and distinct problem, requiring a separate solution. To reach a commercial solution for the beneficiation of any deposit will require very careful study and experimental work on the ore of that deposit. First, work must be carried on in the laboratory and then experiments carried on to duplicate this work on a commercial scale.

The present Iron Ore Committee is, if we understand rightly, to get out its report and recommendations by an early date. Most of the men on this committee are in a position to give only part of their time to the investigations being carried on. It is obviously impossible, under these circumstances, for them to make a specific investigation of the treatment necessary for the beneficiation of the ore of even one of these deposits and they must of necessity limit their report to generalities, comparisons and recommendations. It is for the purpose of aiding the Committee in their recommendations and, if possible, of creating discussion among the men interested in the iron ore situation of Ontario, that these remarks are offered.

## Huge Tonnages Available

The first question that naturally arises is, "Does Ontario contain iron ore bodies of sufficient size and quality to warrant specific investigation?"

To answer this it is only necessary to point out such ore-bodies as the Atikokan, with several million tons of proven ore averaging between 55 per cent. and 60 per cent. iron, but with a sulphur content of slightly over 2 per cent. The Moose Mountain ore-body has an estimated ore reserve of 38,000,000 tons for each 100 feet of depth. This ore contains 36.7 per cent. iron but is high in silica, averaging 45.2 per cent. There is another ore-body of a similar type at the Goulais River. From natural exposures it is estimated that this body contains at least 50,000,000 tons of ore containing 34 per cent. iron and 52 per cent. silica. The Helen siderite body has been proven by drilling and development to contain nearly 100,000,000 tons of ore averaging 35.96 per cent. iron and 2.49 per cent. sulphur. This ore has a loss on ignition of 30.56 per cent. which brings the iron content in the finished product up to 51.79 per cent.

Experimental work for the beneficiation of these ores has been carried on with varying degrees of success. In the cases of the Helen, Moose Mountain and Atikokan deposits, very large sums of money were spent by private interests.

At the Magpie Mine, low sulphur siderite was successfully roasted on a commercial basis for a number of years. Unforeseen conditions on the lower levels of the mine had more to do with the closing down of this operation than any defect in the method of treating this ore.

The treatment necessary for the Helen high sulphur siderite is very similar to that required for the Magpie ore, the variation not being great enough to effect radically the method of operation, so that a close estimate can be made of the cost of treating Helen ore from the data obtainable from the Magpie operation.

Similarly, estimates can be made for the cost of the treatment of some of the other deposits, by a comparison with the successful operations now being carried on, on a commercial basis, at other mines on similar ores.

With undisputed data available to show that Ontario contains very large deposits of low-grade iron ore, the question is: "What measures must be taken to procure a production of iron ore from the Province?"

We might state here that we do not believe that an attempt should be made to obfuscate the beneficiation problem before the Iron Ore Committee, with the problem of exploring or prospecting for iron ore. There are too many prospects throughout the Province that warrant having work done on them, to allow the Government to undertake such work without causing friction with, and unjust comment from, property owners not favored with having such work done on their properties. Any aid given by the Government along these lines should be confined, as heretofore, to the able work of the Geological Branch of the Ontario Department of Mines. This, then, brings us to specific recommendations to deal with the beneficiation problem.

#### *A Practical Suggestion*

To deal with this problem we would suggest the appointment of a permanent commission by the Ontario Government. This commission should consist of a mining engineer familiar with large-scale mining operations and capable of estimating costs on such operations, and a metallurgical engineer, familiar with the beneficiation of iron ores. This commission should have the power to call in expert advice on such problems as transportation and finance when they find it necessary. This commission would be instructed to examine in detail deposits where a large tonnage is proven and report on the feasibility of operating such deposits, with or without beneficiation. We do not think that, at this time, any deposits should be investigated by the commission, unless a large tonnage has been definitely proven.

After the commission have satisfied themselves that a sufficient tonnage is available in a deposit for a commercial operation, their duties would be to definitely determine the beneficiation method necessary on this ore to make the operation of this ore-body a commercial success.

If the commission is satisfied that any deposit can be mined and the ore beneficiated successfully on a commercial basis, they will then recommend that this deposit be operated. They will also recommend the scale on which operations will be carried on, that is, the tonnage of merchantable product.

As the Provincial Government has appointed an Iron Ore Committee to look into the iron ore situation in Ontario, we take it for granted that they are willing to give financial assistance to any operation warranting it. Our suggestions, as to the nature of this assistance, are as follows:

If the commission deems that a deposit can be successfully operated then the Government is to finance the beneficiation and of the operation. The Government

will advance to the operating company enough money to finance a complete beneficiation plant, to handle the ore from the time it passes a three-inch ring until the finished product is delivered on cars. If the Government is willing to do this, it is of course obvious that they must be safe-guarded in their investment. This can be accomplished along the following lines: For the money advanced, the Government is to receive a lien on all of the mining claims on which operations are carried on; the Government to have on the staff of the mining company an accountant who will have access to the books of the company at all times; the Government, should they so desire, may also place on the staff of the mining company an engineer to act in an advisory capacity on the construction and operation of the beneficiation plant.

It is understool that the operating company will take care of all mine development and installation necessary to bring the ore to a three-inch ring, the financial aid given by the Government to be entirely for beneficiation purposes.

We do not think that the Government should demand from the operating company anything more than a nominal rate of interest, and we think that the operating company should be given liberal terms on the amortization of the investment. To be specific, we think that the interest rate should be two per cent, and that the amortization period should cover twenty-five years. This would allow the operating company to repay both the interest and capital at an annual rate equal to five percent on the original investment. It is, of course, necessary in a plan of this nature that both the operating company and the Government be willing to assume their share of the responsibility involved.

Under this plan the company owning the deposit would be required to bring it to such a stage of development that a large enough tonnage of proven ore existed to warrant a commercial operation for beneficiating this ore. They would be required to finance and build a complete plant for mining the ore, should the Government decide to build a beneficiating plant.

The Government for their part would carry on all experimental work connected with the determination of the beneficiation method necessary for the ore of this deposit. They would also finance the erection of the beneficiation plant and all equipment necessary in connection with it, after the beneficiation method had been worked out, the cost of the experimental work on any deposit to be borne by the Government and not to be charged to the total capital expenditure for that deposit. If the Government is willing to do this it seems to us that the company owning the deposit should be willing to safeguard the Government in their investment by giving the Government a lien on the property as mentioned before.

The question might come up as to whether this constitutes a sufficient safeguard. We believe that it does. We think that an operation conceived and planned along these lines offers as sound an investment as the average industrial investment. If through any unforeseen circumstances the project should not prove successful, the Government would still have a claim on an ore-deposit which at some time in the future could be operated at a profit. The known high-grade ore deposits of North America are being worked out at a rate that will eventually cause the lower grade deposits to be operated.

Under this plan the cost to the Government of establishing an iron ore industry in the Province would be hardly nominal. The interest it would receive from the money set aside for beneficiation plants should be enough to cover the cost of experimental beneficiation work and any cost incurred by the permanent Commission, so that the only cost to the Government would

be the loss of interest on money set aside for the construction of beneficiation plants.

If there are any benefits to be derived by the Province from having an iron ore industry established within its borders, such benefits will surely warrant the outlay of the money required under this plan.

#### NEW MINE AT BRITANNIA

This panoramic view of the new camp on the Victoria mineral claim of the Britannia Company, Vancouver Island, is interesting as illustrating the extensive development work that the Company has been carrying on simultaneously with the re-construction of its plant, offices, and townsite at Britannia Beach, all of which were destroyed by fire and flood. The aerial tramway will be noted running from the bunkers near the ore dump. It connects the portal of the main adit on the Victoria with the portal of the 1600 foot level adit of the Empress Mine. The big dumps seen are composed chiefly of ore that has been taken out from the working

openings in the Victoria Mine from the 1900, 2000, and 2100-foot levels as a result of development alone. No stoping has been done.

In the foreground are bunk houses, dining room, recreation hall, store and office of the assistant foreman. There also is the saw mill which has a capacity of 2500 feet of lumber, board measure, per day. In the background are snow sheds and compressor plant and behind the tramway may be seen the top of the shaft-house over the Victoria shaft.

Work was commenced on this camp on June the 24th 1921, in the virgin forest and the photograph was taken some two months ago.

Victoria Mine, Britannia Mining & Smelting Company, Vancouver Island, B. C.

#### BLANCHE RIVER AREA

##### *Geological Report Issued*

The Ontario Department of Mines has now ready for distribution Part 3, Vol. 31, 1922 — *Blanche River Area* by A. G. Burrows and P. E. Hopkins. The map accompanying this report was ready for issue over a month ago and was noticed in these pages on December 15th. The report comprises 22 pages, well illustrated with photos and diagrams. The field work was done mainly in the summer of 1921 and was completed in May, 1922, so that the issuance of this report so soon after the field work was finished reflects the greatest credit upon the Department.

The central part of the area was, before the disastrous fires of last October, a prosperous farming community. The clay ground in the valley of the Blanche River and its tributaries is eminently suited for agriculture, and constitutes a small clay belt, subsidiary to the great clay belt to the north through which the Transcontinental Railway runs.

The only productive mining of the region has been at the *Coney Cobalt Mine*, north of Lake Temiskaming, which has produced about three million ounces of silver. On the eastern shore of the Coney Silver Mines in Coney township

on the Montreal River, some small shoots of high-grade silver ore have been found and a few tons shipped to Cobalt. Venis on the property of the Triangle Silver Mines in Auld township also show bunches of rich silver ore.

Gold has been found so far only in Bryce township, in the western part of the map area, where shear zones carrying values in gold occur in light-colored volcanic rocks of Keewatin age. In Bayly township, adjoining Skead in the northern part of the map-area, there is an area of the andesite rock that is known to contain gold in the latter, but no gold has yet been found in Bayly township.

Wendigo Lake, on the old canoe route to Larder Lake, shares with numerous other localities a fame for cobalt bloom — *without* silver. Of present interest is a water-power available at its discharge, partly developed by the Canadian Associated Goldfields interests.

At Charlton a hydro-electric plant furnishes 1200 horsepower for the Kirkland gold mines. It is pointed out that a fall of 138 feet on the north branch of the Blanche River in Marter township, lot 2 (11!) Con IV will develop 2,000 horsepower.

# Bank of Commerce and Mining

By ALEXANDER GRAY

The Annual Survey of Sir Edmund Walker is true to the text. For twenty years, even since the discovery of Cobalt, the Bank of Commerce has annually demonstrated by official utterances that it is the consistent advocate of sound mining, and more of it, if mineral resources are to function for the common weal. Year after year, primarily advised by the fully-informed Logan—at first Branch Manager at Cobalt and now chief of the Foreign Exchange Department—the Canadian Bank of Commerce has spoken without the aversion that has militated against mining among those who could have lent the weight of their influence and capital in behalf of development without resort to scrambling for small change.

Personally identified with a section of the Nickel Industry, Sir Edmund Walker has been in a position to speak with first-hand knowledge; therefore it is altogether refreshing to have him reassert his confidence in mining in industrialism and to urge what other bankers are so chary about prescribing as a remedy for Canadian shortcomings. The Royal Bank, the Bank of Montreal and once more the Bank of Commerce, having admitted diversified mining to the charmed circle of domestic capitalists, perhaps, when the Dominion gets its bearings and bankers have a freer hand, well-conceived mining ventures will be regarded with less suspicion and banks will not be censorious toward customers engaged in mining.

Not so long ago a banking directorate, altogether pleased with the accretions from bullion going forward to American mints, had half a doubt lest "gold bricking" be possible, since advances were being made against ingots in transit through the bank. Instantly an order was given to bring some of the bullion briquettes from the bank vaults. To the astonishment of the assembled directors, whose misgivings were accentuated, the gold bars were so discoloured that they conveyed no hint of their precious character. "Is that gold?" ejaculated one skeptical arbiter of our fiscal destiny.

The incident serves to emphasize what leading bankers now are beginning to comprehend. Before the mineral deposits of the Dominion can attain to the dignified status they are entitled to, it is essential that the Bankers Association give due prominence to precious metal miners as the sources of wealth without which the balances are out. At the moment, when the world wants the funds, the Witwatersrand is producing over \$500,000 each day, the highest financiers realizing that money in circulation is infinitely more useful than gold in the ground. Nearly 800,000 ounces per month is coming from those gold mines, while Canadian politicians quibble about providing power facilities and whittle appropriations for geological and mines departments. Now we have forcible response to those who decry mining. "What is Hollinger, anyhow?" petulantly queried one branch manager a few years ago, when a client sought a small credit and tendered Hollinger shares as security. His chief has recently made answer. Without the 8,330,091 ounces of gold in 1919; 8,153,625 ozs. in 1920; 8,114,586 in 1921, and about 7,000,000 ounces in 1922 (altogether the first two months of the last year was somewhat of a blank owing to the miners' strike,) South Africa would be disconsolate, and international exchange less stable. The Rand is making records. Ontario and British Columbia are prepared to proceed with larger operations—and for this we have these remarks of Sir Edmund Walker:

## *Increase in Gold Production*

"It is in gold mining, however, that we are making the most striking progress and attracting the most attention from the outside world. The increase in production for the year is about 31 per cent as compared with 1921, and the output of several of the most important mines is being enlarged and promises to be much greater in future. Ontario leads the other provinces as a producer of gold and indeed of metals as a whole, and she has now passed California in gold production. Our gold production is as yet only small in proportion to that of the Transvaal, but one mine alone contemplates an increase in production which would very largely affect this comparison. We have passed the period of low prices for metals, which reached a climax in 1921, as well as the worst point in the world wide depression of general business, and while the markets for some minerals are as yet far from normal, we may on the whole look forward to an increase in both production and profits.

## *Our Coal Mines*

"The year has been an unsuccessful one for the coal mines of Western Canada. There the mine owner is struggling with strikes, high labor and transportation costs and a small market, made still smaller by cheap oil. Some day the abundant coal measures of British Columbia, Alberta and Saskatchewan will entirely supply all of Western Canada from the head of lakes to the Pacific, as well as a large ocean-borne trade, and a trade with the United States, and perhaps with Ontario; but while oil is cheap, population thin and transportation dear, the development of all this natural wealth is surrounded with difficulties. There should probably be fewer mines, so that the natural prosperity of those most favorably situated would not be prevented by the competition of those which have little chance of success. The mines of Nova Scotia and New Brunswick, on the other hand, cannot, as yet, produce enough coal to lessen, as we certainly should as far as possible, our coal imports from the United States. These imports, mostly for the use of Ontario and Quebec, constitute about 60 per cent. of our consumption of coal.

## *Mines and Transportation*

"The newer countries of the world are apt to be known in the world's trade circles by some main product upon which their prosperity, or the lack of it, principally depends. Canada is classed as a wheat country, and it will doubtless be found that our prosperity depended in the past largely on the quantity of our wheat crop and its price. We are, however, year by year attracting the attention of the world to the position of Canada as a mining country. The products of mining show more readily than almost any others that the ultimate money value of any commodity depends on the cost of transporting it to a market. We have more coal than any country in the world, except the United States, but the high state of development of water-powers, "white coal," as we call it in Ontario and Quebec, where no coal exists, is the evidence of our inability to transport coal from other provinces, and the bill for the coal we buy from the United States is one of our serious national burdens. Some day the improvement of our waterways will materially change this and, similarly, the growth of our population, our industries, and our systems of both land and water transportation, will make it profitable to mine many ores which have no money value just now. Gold, silver and a few other ores will, when refined, or partly

so bear the cost of transportation and these are, therefore, the first loss of the prospector.

#### *Mineral Possibilities*

In the remarkably thoughtful address of the late president of the Canadian Institute of Mining and Metallurgy we are reminded that while we are a great factor in the world's food supply, this comes from the partial development of about fifteen per cent. of the area of Canada, while in the remaining eighty-five per cent., and to some extent, of course, in the fifteen, we have 'mineral treasures of inconceivable value.' The selection of land for agricultural or pastoral purposes is one of the easiest tasks of the adventurer, the discovery of a real mine one of the hardest, apart from the few cases where men have found fortunes by sheer accident. Twenty or thirty years ago we had little experience or training in mining, and a good deal of what we have now arises from the success attained in mining in the United States. In South Africa, however, there are many miners, both those who hold executive positions because of scientific ability and those who have owned mines and are not afraid of such ventures, and we have reason to hope that some of the leaders among these men will become interested in our north country.

#### *A Wonderful Heritage*

For three-quarters of a century our geologists and other Canadians of reasonable intelligence have known that we possess in central Canada the largest area in the world of the oldest rocks and of the rocks immediately following these, all roughly classed as pre-Cambrian. These are most promising areas for the prospector, but we also possess in the Maritime Provinces and Eastern Quebec our share of the Appalachian mountains and in the far west our share of the vast Cordilleran areas. Of gold, silver, nickel, copper, asbestos and other metals we are already important producers. We have iron ores in plenty, but these are not so readily available as the ores mined in that comparatively small extension of our pre-Cambrian area into the United States, which is so wonderfully rich in iron and copper as to be famous throughout the world. What we have accomplished thus far in the three great mining areas has been largely the result of accident; we can hardly pretend that there has been serious prospecting in many of the mining fields of Canada, except by a very small number of trained experts. The Cordilleran or Pacific mountains in Canada form an area about as large as the pre-Cambrian in the centre of Canada, and of this the late President of the Canadian Institute of Mining and Metallurgy says: 'Does anyone know of any sufficiently sound reason, even after allowing for certain known differences of glaciation and geological formation, for thinking that Canada's share of this great area will prove to be less rich in minerals than that falling to Mexico or to the United States?'

This coming from one of the trio of leading bankers, it remains to quote an extract from the year-end comment of deputy Minister of Mines, Gibson:

"There seems at the present no reason to doubt that the mines both at Porcupine and Kirkland Lake may, notwithstanding increased production, go on year by year, increasing the amounts of ore in reserve. This affords the best of reasons for increasing their capacity for turning out bullion."

But where is the necessary hydro-electric power and the pre-requisite capital?

No one worthy of trust wishes to have banks take unnecessary risks or to countenance over-speculation; only the reckless would like to have them ignore factors of safety. That, however, is not an issue, because the banks will

adhere to correct principles. It is in the policy of frowning upon prudently conducted mining enterprises, that the banks go to the other extreme. They are rather chary just now of all industrial movements, and it was in this connection the other day that Charles M. Schawb addressed the New York State Bankers Association and said:—

"Why should the banks discriminate against the industrial securities? They are founded on the ability and integrity of those who manage the industries, they are founded on the future of the country. All the money of the United States Government will not be enough to support the industry of the country in the future."

Mr. Schawb speaks as the father of a giant corporation, a mining and manufacturing Goliath. He operates mines and mills, in North America, South America, and Cuba. He speaks with force to bankers.

### LETTERS FROM READERS

#### *Mr. Holding Objects*

To the Editor, Canadian Mining Journal:

Sir:—My notice has been attracted lately to your articles on wild-catting, and the unscrupulous way in which mining companies are being organized for the sole purpose of milking the public. I have had more than my share of experience with one of these to which your article might have been meant to apply, and this might lead some people to believe that I am one of the principals in the undertaking alluded to.

I refer to a newly organized company, under the name of the "Holding Consolidated Company, Limited." I would like to clear myself of any unjust imputations by stating a few facts.

I was the discoverer of the Holding mining claims in the West Shining Tree district, and still hold 75 per cent. interest in them. These claims were optioned to others, and I have had no hand in the incorporation of the company alluded to. I have endeavoured by every means possible to prevent any manipulation by which any person could be deceived.

My claims were, and still are under the incorporated name, Asquith Gold Mining Co. I had no knowledge of the Company mentioned above until I saw it in print.

ROBT. HOLDING.

Chapleau, Ont. ,

The "Turf" shaft of the Village Deep mine is the deepest on the Rand, South Africa, if not in the world. Its vertical depth is 6,263 feet, which is 629 feet below sea level. During November last it produced 59,000 tons of ore, averaging 6.8 dwts. in gold, at a profit of £20,000.

With a total production capacity of about 12,000,000 tons of pig-iron per annum, the United Kingdom made during 1922 only 4,865,000 tons, which is, however, a notable advance over the 2,616,300 tons of 1921. The price in Britain is now only 25 p. c. in advance of that prevalent before the war.

The antimony mines of China have for many years furnished more than half the world's supply. As the ores are, in general, low-grade, it is not likely that the present price of antimony will be reduced materially.

# The Province of Quebec

The Largest Province of Canada, Great Timber Areas,  
Mineral Wealth and Water Power

By Lt.-Col. P. PELLETIER, Agent-General for Quebec,  
in "Raw Materials Review" of London (Eng.)  
(Abridged)

The Province of Quebec, the most easterly portion of the Dominion, comprises one-fifth of the total area of Canada, and is 703,653 miles in extent. Practically maritime, stretching along both sides of the great St. Lawrence waterway, it is the ocean gateway into Canada, and for eight months of the year all exports from the Dominion to European markets and all Atlantic borne imports into the country, pass through the sea-ports of Quebec and Montreal.

The great potential wealth of this Province is in her timber, and timber products, mineral wealth, and great water powers.

\* \* \*

## Minerals

No adequate estimate in money value can be made of Quebec's potential mineral wealth, because only a small fraction of the mineral deposits have been prospected. Stretching across the northern part of both Ontario and Quebec is an enormous pre-Cambrian area, nearly surrounding Hudson Bay, and occupying more than half of the entire surface of the country. It is the greatest single exposure of the earth's basement in existence.

A small spur of this area, amounting to about three per cent. of the whole, projects into the United States, south-west of Lake Superior. Small as the spur is, it produces annually more than 80 per cent. of the entire output of iron ore in the United States. When one considers that the Province of Quebec extends north to Labrador along the whole length of the eastern shore of Hudson Bay, taking in the greater portion of the pre-Cambrian area, one feels justified in thinking that the metals and minerals of Quebec are practically inexhaustible. A conservative estimate places the area covered by this ancient series of rocks as 90 per cent. of the entire Province.

Quebec, however, has not yet seriously turned attention to the exploration and geological mapping, much less to the prospecting, of this huge area. The attention of the Quebec mining men has so far been largely directed to the rich mineral deposits of the Acadian Highlands, which occupy the Eastern Townships and Gaspé Peninsula on the Gulf of St. Lawrence. In these areas asbestos, chrome, pyrites, copper, lead, zinc, and gold ores are being or have been mined.

In those parts where geological examination and prospecting have been carried out, deposits of iron, copper, nickel, gold, and silver has been found. Over much of this mining area in the north of the Province, lumbering will for many years be an important industry, as much of the area is covered with valuable forests.

\* \* \*

## Asbestos

Quebec produces 88 per cent. of the asbestos of the world. The output for the year 1919 was 136,199 tons valued at £2,200,000, and in 1920 the output had increased to 199,573 tons valued at £2,958,440. Trade

depression, which is world-wide, seriously affected this industry, and in 1921 the shipment of fibre amounted to 87,475 tons valued at £1,039,957, the lowest record in output since 1910 and the lowest in value since 1916. This constituted a decrease of 51.3 per cent. in tonnage and 64.7 per cent. in value. The stocks on hand, stored in mill-sheds at the close of 1921, amounted to 53,345 tons.

At a time when a great endeavour is being made toward inter-Imperial trade, it is interesting to note that, while the British Empire produces, up to the present, the raw asbestos of the world, the United States ranks first in the production of manufactured asbestos articles.

## Mica

Canada ranks second in the world-production of mica, and the Province of Quebec produces 80 per cent. of the total Canadian production. The province possesses almost a monopoly of phlogopite mica, the deposits of the greatest economic value occurring within an area of 520 square miles in the Gatineau district directly north of the city of Hull.

Mica is a crystalline silicate of aluminium and other metals, notably potassium, sodium, magnesium and iron. It is either mined or quarried, and comes out in blocks of crystalline layers, which are split into thin plates. The commercial varieties of mica are muscovite or potash mica, and phlogopite or magnesia mica. Until recently only sheet-mica measuring 2 by 4 inches was of commercial value, the smaller stuff going on to the waste heap.

A process has been established whereby mica sheets can be built up from thin plates of scrap mica pressed together by hydraulic pressure and cemented with shellac into sheets of any thickness and size required. Such material is known upon the market as "Micamite," and is now replacing to a great extent sheet mica in commutators, especially in large machines. This new material is widely used, and is produced in large quantities, finding a ready market for all insulation purposes. Finely-ground mica is also used in paints and lubricants, thus all waste has been eliminated.

The production of mica for the year 1921 was the lowest since 1898, only 288,197 lbs. being mined valued at £8,444. Of this amount the United States took 88 per cent., England 10 per cent., and other parts of the world 2 per cent.

## Titanium-White

Titaniferous iron ore occurs in very large quantities on the north shore of the lower St. Lawrence as well as north of Montreal in the Laurentian plateau. It is proposed to use titanium compounds derived from this ore largely in paints to replace white lead.

The titanium-white is prepared by pulverizing the ilmenite and treating it with hot commercial sulphuric acid, thus forming sulphates of iron and of titanium, which are soluble in water. On ebullition, the titanium hydrate is precipitated. This is neutralised by

barium carbonate and calcined. Another method used consists in fusing ilmenite in an electric furnace with fluxes.

Titanium white has a very high index of refraction, and consequently high covering power; it is not poisonous, and with linseed oil it gives a paint which is not acted upon by sea water. One kilogram of titanium white is estimated to cover 20 square metres, whereas one kilogram of white lead covers only 9.1 square metres.

#### *Feldspar*

Feldspar production is increasing to a remarkable degree, and is an assured industry. In 1920 only 849 tons were produced, valued at £2,250, while in 1921 this had increased to 9,797 tons, valued at £15,950. A rich deposit is being worked north of Buckingham. It is situated 300 feet above the level of the valley, and is opened in two benches showing a combined height of 40-ft. face. The deposit shows a width of 50 ft. of workable spar, and is 300 ft. along the strike. The spar, as now shipped, is practically pure orthoclase. The analysis shows 10 to 13½ per cent. potash, 1 to 1½ per cent. soda, and 4 to 5½ per cent. free silica.

#### *Other Minerals*

Chromite is produced in paying quantities, and oil shales occur throughout the Province. Quebec has rich quarries of marbles, and building materials of various kinds. The products of the quarries during 1920 amounted to £2,410,971, and were made up of slate, clay, sandstone, granite, marble, and limestone.

The amount of limestone produced in 1921 was 1,007,733 tons, valued at £304,605, while the marble for the same year was valued at £33,532. Lime and cement are produced in large quantities, the cement output for 1921 being 2,135,631 barrels, valued at £1,082,053. The manufacture of cement is one of the important industries.

Granite quarries produced £100,000 in 1920, and brick making is carried on extensively. Slate and sand are produced in large quantities.

Concrete is used largely in all the construction work in the Province. Molybdenite occurs in large quantities, and is used extensively in the steel industry, especially in producing steel for automobile parts. Zinc and lead, as well as gold and silver, are produced, but as yet in small quantities.

Quebec is one of the chief producers of aluminium, and has at Shawinigan Falls one of the largest aluminium plants in the world, although as yet no bauxite has been found in the Province.

\* \* \*

#### *Water-Power*

Nature has deprived this province of coal, but in its place she has endowed Quebec with such a wealth of water-power that in the natural course of events the Province should develop into one of the greatest manufacturing centres in the British Empire.

According to the latest estimate of the Department of Lands and Forests, the gross water-power of the rivers is probably 15,000,000 horse-power. Two important dams have already been built, while the Gouin reservoir on the Upper St. Maurice River constitutes what is one of the largest reservoirs in the world. Its capacity when full is 160,000,000,000 cubic feet, and

the water area is 300 square miles. This storage permits of a regulated permanent flow of over 12,000 cubic feet per second at Shawinigan; or in other words a capacity for developing regularly 1,000,000 units of power.

The St. Francois dam, although of less importance, stores 12,000,000,000 cubic feet at its fullest capacity, and will prove of great value to the numerous pulp and other mills along its water course. It is estimated that if a dam were built at the outlet of Lake St. John, the water-powers on the Grande-Décharge or on the Petite-Décharge would be increased to 800,000 horse power.

The principal hydraulic plants have installed turbines capable of developing 823,274 horse power. It is estimated, according to Government reports, that the capacity of the water-powers at present developed in the Province, is 900,000 horse power. The electric current from these great plants is carried hundreds of miles on great steel towers into the various municipalities, for use in industrial concerns.

Many of the municipalities grant tempting bonuses and tax exemptions to capitalists, in order to induce them to establish manufacturing plants in the various districts. Municipal councils in Quebec have the substantial backing of the Government, and on March 4, 1918, a Department of Municipal Affairs was created with a Minister in charge. This represents a new departure in Governments but one calculated to create confidence in investment in the Province.

In this Province Government revenue always exceeds expenditure and taxation is low. Labour is well organised under the present system and strikes are practically unknown.

#### MINING EQUIPMENT FOR BINGO MINES

Bingo Gold Mines, Limited, have just placed an order for a complete mining plant with Engineering Equipment Co., Ltd., of Montreal. Mr. J. A. Davis, of Engineering Equipment Co., has just returned from a visit to the mine, which is on Herb Lake, 23 miles from mileage 82 on the Hudson Bay Railway.

After an early experience with stock-jobbing that resulted in little actual work on the claims, the Bingo property passed into the control of London investors and now is being explored systematically by them. Dr. J. S. DeLury, of the University of Manitoba, has examined the gold showings thoroughly and has reported very favourably on the prospect of their providing sufficient ore to make a paying mine.

A shaft is down about 200 feet and from this shaft it is proposed to explore and develop the ore-shoots of a series of small parallel veins that show very promising values at the outcrop. The installation of the new mining plant will mark the commencement of a vigorous campaign of development on this, one of the more promising of the gold prospects in Northern Manitoba.

Before the war Germany imported about half her requirements of nitrates. During the war nitrogen fixation processes, notably, that of Haber and Bosch were applied industrially, and now are capable of supplying Germany's full need if worked to capacity. Their production in 1922 was 300,000 tons of synthetic nitrates, and it is estimated that the production for the next year will be 350,000 tons.

# Salmon River District, B. C.

## REPORT ON GEOLOGY OF AREA CONTAINING PREMIER MINE

The Geological Survey, Ottawa, has just published Memoir 132, *Geology and Ore Deposits of Salmon River District, British Columbia*, by S. J. Schofield and G. Hanson. This report of 73 pages is most important and timely. It includes a geological colored contour map on a scale of 4,000 feet to the inch, six sketch maps and six photos. The region was studied by J. J. O'Neill in 1919 and by Messrs. Schofield and Hanson in 1920. The final chapter comprises a brief general study of the ore-deposits of British Columbia, which forms an excellent basis upon which to build up a detailed knowledge of the Province's various mineral deposits.

The map area, 11 miles north of Stewart, at the head of the Portland Canal, contains the Premier mine and the International, Bush, Indian, Big Missouri, Mineral Hill, Spider, Hercules, Forty Nine and other prospects. The Premier is the only producing mine so far.

### Geology

The Salmon River area is near the eastern edge of the Coast Range batholith. The rocks are principally sedimentaries and volcanics of Jurassic age which were folded and then intruded by the huge batholith in late Jurassic times, and subsequently denuded. The ore deposits are connected with minor intrusions that marked the last phase of the batholithic intrusion.

In discussing the general aspect of the district's economic geology, the writers make this most important statement: "The geological conditions which surround the Premier extend hundreds of miles north and south, along the eastern flank of the Coast Range batholith, and it is most probable that other properties similar to the Premier will be discovered in this large unprospected area. Keno Hill in the Yukon, the Engineer mine of Atlin, and the Dolly Varden mine of Alice Arm, are other properties in this great belt of mineralization. The occurrence of such high-grade ore as occurs in the Premier mine proves conclusively that there are ore-bodies in British Columbia that can be made to pay from the outcrop.

"Most of the ore-bodies are associated with the quartz porphyry sills at their intrusive contact with the tuffs of the Bear River formation . . . . The most favorable geological conditions for the occurrence of ore in Salmon River area appears to be found at the following places: At the contact of the quartz porphyry with the tuffs; in certain beds of the tuff and tuffaceous conglomerate; in the quartz porphyry sills. The slates, although mineralized, do not appear favorable for the deposition of commercial ore-bodies." These statements constitute practical directions for prospectors or for geologists or engineers directing the operations of prospectors.

### The Ore Deposits

The characteristic minerals of the deposits are native silver and gold and a long series of sulphides and sulpho-salts rich in silver.

As at the Dolly Varden mine to the southeast, secondary enrichment has played an important part in producing the bonanza ore of the Premier. The geological studies indicate that, though the high silver

values are likely to cease within a few hundred feet of the surface, as at the Dolly Varden, the Premier ore is likely to carry good gold values to a much greater depth.

In discussing the ore-deposits, the writers distinguish between the following types:

(a).—A low-grade, complex type, with values in the base metals, copper, lead and zinc. (Big Missouri, Hercules, Forty-nine, etc.)

(b).—A type rich in silver minerals, including tetrahedrite, freibergite, pyrrargyrite, argentite, and in some cases native silver. (Premier, Silver Tip, certain ore-bodies on Forty-nine, Big Missouri and Mineral Hill.)

(c).—A pyritic, siliceous type with high gold values. (An ore-body in Premier mine).

It is stated that the sulphides rich in silver, such as tetrahedrite, freibergite, argentite, and some of the pyrrargyrite are of primary origin and will continue in depth. The native silver is of secondary origin.

### A Geological Study

The final chapter on *Ore Deposits of British Columbia*, by Dr. Schofield, compresses into ten pages an unusually informing and suggestive study of the province's principal mineral deposits. He divides the mineral history of British Columbia into two periods, that from 1871 to 1905 being the "exploratory period" during which the pioneer geologists discovered and correlated the main facts of the region's mineral deposition and delineated the zones favourable for prospecting; and the second period, from 1905 to the present, characterized by intensive geological study and active exploration, during which time most of the ore-deposits now known have been found.

The province's great mineral-bringer has been the batholithic intrusion that skirts the coast and then swings inland along the international boundary. The deposits on either side of this intrusive mass are characteristic of that side. To the west the ores are mainly copper-bearing, while to the east and north they contain mainly gold, silver and lead. To the west are Anyox, Marble Bay, Quatsino Sound, Sunloch, Britannia; to the east are Salmon River, Premier Mine, Bear River, Alice Arm, Dolly Varden mine, Hazelton (excepting Rocher Déboulé), and the deposits in the Ota Lake and Whitesail Lake areas. In the interior the same distinction holds, the Boundary belt including Copper mountain, Phoenix, Deadwood, and Rossland, while the northern or Kootenay belt includes Ainsworth, East Kootenay (Sullivan, North Star, St. Eugene), Slovan, Lardeau, Revelstoke and Stump Lake.

A geological study gives a good reason for this difference. The great batholithic intrusion and its flanks have been cut (by erosion) in a plane at an angle to the original surface, dipping toward the east, thus exposing the eastern flank at a greater depth than the western. Thus it happens that the western flank, characterised in general by roof pendants and a high degree of metamorphism, has copper deposits characteristic of conditions of high temperature and pressure, while the eastern flank has geological and mine

ological conditions characteristic of the lesser metamorphism that can be expected on the sides of an intrusion.

Unlike the ore deposits of the great pre-Cambrian area of central and eastern Canada, those of British Columbia are connected almost exclusively with the intrusive period of late Jurassic times. The intrusion has, fortunately for the province's future mineral production, stretched along two sides, the Pacific and the

international boundary. Bearing in mind the ore-deposits already determined in this huge area of potential mineral production, Dr. Schofield is ready to commit himself thus: "Subsequent to, and largely because of, the labour of these men [the pioneer geologists], a great mining industry has developed and there are enough good prospects in sight to warrant the statement that the industry will grow with an ever increasing speed."

## Raw Material for Fertilisers in Canada\*

(Specially Contributed by Natural Resources Intelligence Branch.)

At the present time Canada's main supply of nitrogen, most of the phosphorus, and practically all the potash used in the fertiliser trade is drawn from outside sources, but if it were economically advisable or necessary, the Dominion could provide for her needs at home. Subsidiary materials, such as sulphuric acid, gypsum, and other forms of lime, are staple home products.

The following is a resumé of all the materials at present known to exist in Canada as available for fertiliser, and a distinction will be drawn between these now active and those dormant or potential or neglected.

### Nitrogen

Leaving out of sight the nitrogen supplied by abundant rain and snow and the leguminous crops and barnyard manure common to every farming country, and also the local "mussel mud" of Prince Edward Island, the sediment deposits on dyked lands, and the sewage going to waste, the largest active sources of nitrogen in Canada now are four—namely, abattoir waste, fish and whale waste, ammonium sulphate from by-product ovens, and cyanamide from fixation of air. Abattoir products, including dried blood and tankage, are the only fertiliser materials produced between the western boundary of Ontario and the Rocky Mountains. The bulk of abattoir products is found in Ontario, as might be expected where a meat-eating population is denser, and where fertiliser is more in demand than elsewhere.

Of nineteen fish-waste and whale-products factories producing "fish guano" fifteen are on the Pacific coast of British Columbia. Most of these are dependent on the canned salmon industry for their supplies of offal, but the Consolidated Whaling Corporation has three whaling stations (on Queen Charlotte and Vancouver Islands), and there are various attempts to utilise the herring, dog-fish, and sharks that abound.

Conditions are different on the Atlantic coast. Though the number of fish-curing establishments in the maritime provinces is more than three times the number of those in British Columbia, there are only four factories for fertilisers. This is due to the separation of fish-curing depots at wide intervals along the coasts, as opposed to great concentration in British Columbia, to deep sea fishing as opposed to that at inlets and rivers' mouths, and to the considerable proportion of shell fish.

Taking the fish industry of Canada as a whole in relation to fertilisers, the figures available for 1920, indicate strikingly the neglect of fish-waste as a source of fertiliser. It can be seen that in New Brunswick and Quebec the only use made of fish as fertiliser was to dispose of 73,689 barrels of surplus fish for spreading on the land. The 930 canneries or fish-curing places (excepting the phosphatic material of bone meal, mainly from whales) produced on an average about one-half a ton each of nitrogenous fertiliser. Further evidence of the waste of fish meal as guano is found in the very large proportion of oil produced and sold, as compared with fertiliser material produced from the same source. What becomes of the by-products, whose value is so greatly increased by the extraction of the oil?

Seven plants produce ammonium sulphate, the chief of which are those of the British Empire Steel Corporation, in Nova Scotia; the smelters of the Granby Consolidated Smelting and Mining Company, Anyox, in British Columbia; the Algoma Steel Corporation at Sault Ste. Marie, Ontario; and the Steel Company of Canada, at Hamilton, Ontario. For Nova Scotia the chief market, besides the apple orchards of the Annapolis Valley, Nova Scotia, is the West Indies; for British Columbia, besides the orchard districts of the province, Hawaii, the Dutch East Indies, and Japan. Ontario producers have a market in the large fruit district of the Niagara peninsula. Small supplies of ammonium sulphate are also drawn from the lighting, heating, and power gas industries of Montreal and some other towns.

Of the processes for fixation of atmospheric nitrogen Canada furnishes two examples. The American Cyanamid Company, utilising the Niagara power, produces about 63,000 tons of cyanamid yearly, but the whole product is shipped to New York for treatment and sale. An arc process plant, utilising the Lake Buntzen power in British Columbia, has a capacity of 800 metric tons of nitrogen a year, but the final product is in the main sodium nitrite, and not in nitrate form.

Though the present active production of nitrogen is on the small scale indicated, Canada has reserves of power and material which will make her a factor in the market when the world's needs of nitrogen, which double every ten years, are pressing on supplies. The non-active reserves for nitrogen in descending order lie—(1) In the water powers with the requisite abundance of coal and lime; (2) in the extensive area of oil shales; (3) in the vast fields of lignite, bituminous coal, and peat.

\*From Raw Material Review, London.

### Phosphorus

Active production on any considerable scale is now confined to animal refuse, fish waste, and basic slag. What is produced apart from the bone ash and bone black of sugar refineries, beet sugar waste, brewers' waste, and apatite is insignificant.

Bone meal is a product of abattoirs and the whaling industry, and a percentage of phosphate is also found in the guano of fish waste. The location and character of these sources of supply have already been noted in connection with nitrogen. The third active supply is from basic slag. The general disuse of the Bessemer process in the manufacture of steel and the substitution of the basic open hearth process, with or without the use of fluorspar, has affected the amount of available phosphorus in the slag, and given rise to experimental work proving the value of the different types, the verdict being that if the purchaser considers the unit of phosphorus and the fineness of grinding, the value of each type is the same. Apart from a small importation (valued at \$18,000 in 1921) from the U. S. A., the slag used as fertiliser in Canada is produced at the blast furnaces in Nova Scotia and Ontario.

### Potash

Canada is estimated to consume annually 1,200 tons of actual potash ( $K_2O$ ), which is equivalent to about 6,000 tons of salts. Nearly all of this is imported from Germany, Alsace, and the United States. The breaking of the German monopoly by the restoration of Alsace to France and by the development of potash

resources in the United States during the war has been of great benefit to the consumer. The natural brines and deposits of Nebraska and California and the Alsatian mines are now rivals of the Stassfurt Syndicate in the potash market. This being the case, active potash production in Canada is merely a side issue, if we except the wood ashes exported for other than fertiliser purposes to the United States. Potash is recovered from fine dust in one or two cement plants and from blast furnace gases, and small amounts are still saved at the three beet sugar factories in Ontario and at certain distilleries. As a by-product of wool scouring, it is likely to increase now that the Co-operative Wool Growers are centralising the yield and a combing plant company is projected on similar lines.

### Sulphuric Acid

This is manufactured largely (1920, 73,000 tons) from the pyrites of iron and copper, which are widespread in Canada. Some is exported. Judging by United States statistics, 60 per cent. of the output is used in the fertiliser industry.

### Limestone, Marl and Gypsum

As needed for fixation processes of atmospheric nitrogen or for soil improvement, such as neutralisation of acids, development of useful bacteria, and general physical condition, limestone and marl deposits are widely distributed, except from western Manitoba to the Rocky Mountains. Gypsum, however, is found in northern Alberta.

## United States Coal Commission--Interim Report

*The United States Coal Commission has made an interim report to Congress, from which these salient paragraphs are taken. This report is of moment to Canadians not only because it affects the principal source of our coal supply but also because it describes conditions that prevail in Canada as well as in the United States.*

### The Public and Coal

The coal problem begins with a contradiction. Rich beyond all other nations in its wealth of coal resources, the United States experiences coal shortages and high prices. The coal deposits of the country are abundant and well distributed. Coal of every variety from anthracite to lignite underlies the hills and plains and mountains in beds whose content is measured by thousands of billions of tons, so that coal of a quality and in quantity that would be regarded as important by most other nations is found in all but thirteen States of the Union, and commercial mines are being operated in twenty-nine States.

Yet, with resources of coal in the ground adequate for the needs of perhaps a hundred generations of Americans, the nation's coal bin is too often depleted and too often the prices paid for coal are much higher than seem warranted by the wealth of coal available.

There have been during the last six years three periods when shortage in the supply of coal has given rise to acute national concern. These recurring periods of scarcity have increased the cost of this basic commodity—increases especially serious to domestic consumers, railroads, and public utilities. These experiences of unsatisfied demand and unsatisfactory prices have created in the popular mind a conviction that the natural benefits to be expected from a

condition of plenty have been denied through artificial interference. The coal industry, therefore, has been subjected to outspoken criticism, and public dissatisfaction has expressed itself in a series of investigations and in regulatory laws.

The Act creating the United States Coal Commission is an expression of this feeling of public concern and dissatisfaction.

### The Coal Industry

Every industry and every citizen throughout the country is directly or indirectly dependent upon coal. While it is true that a large majority of the States have coal mines within their limits, it is significant that all the anthracite comes from a narrow area of 480 square miles in eastern Pennsylvania and 93 per cent of the bituminous coal comes from three major areas: The Appalachian region, extending from Pennsylvania to Alabama, the greatest storehouse of high-rank coal in the world; the Eastern Interior, comprising Illinois, Indiana, and Western Kentucky; and the Western Interior region, extending from Iowa to Arkansas and Oklahoma. Any map showing the distribution of the larger industrial plants of the country would in itself demonstrate the part played by these coal fields in locating the great manufacturing centers and planning the network of railroads that connect the larger commercial cities with the rich agricultural lands of the West and South. Inasmuch as more than two-thirds of the country's supply of high-grade coal lies within these three great coal areas, they may well be regarded as its chief known sources of industrial power for future centuries. The coal problem of the country, so far as it relates to present production, then, is largely localized in three coal regions and about a dozen

States, although it is recognized that each mining district, large or small, has its problems to be investigated.

In reality the coal industry includes three interrelated industries—mining, transportation, and marketing.

The coal mining industry, in point of numbers employed, outranks any single manufacturing industry and stands next to transportation and agriculture. Approximately three quarters of a million men are employed in this industry, of whom 90 per cent work underground.

The capital invested, according to the rough figures of the census, is \$2,330,000,000 of which \$430,000,000 is invested in the anthracite region and the remainder in the bituminous fields. There are only 174 producers of anthracite and 8 of these control over 70 per cent of the annual output, while there are at least 6,000 commercial producers of soft coal, to say nothing of thousands of wagon mines and country coal banks. These producers operate 9,000 commercial mines.

While the anthracite and bituminous branches of the coal industry are to some degree competitive in their markets, the differences in their mining, labor, and economic problems are so marked that the discussion in this report will be limited to bituminous coal except where anthracite is specifically mentioned; the law requires a "separate report on the anthracite industry on or before July 1, 1923."

Each coal district, if not each mine, has its own local customs and problems, determined by the quality of coal, thickness of seam, attitude of the bed, conditions of mining, the markets which it can reach, its freight rates, its labor policy and other factors. In the matter of wage scales, even in the union districts where wage scales are determined by joint agreement, we find variations from district to district and from mine to mine. Still more difficult to summarize are the wage rates in non-union mines. Not only are these wage rates complicated, but the opportunity to labor varies so greatly from field to field or mine to mine, depending on character of coal, nearness to the market, and commercial connections; that it is hazardous to make any generalization concerning miners' earnings.

No less difficult under such conditions is the determination of average cost or profit. These subjects require specific and very detailed, painstaking investigation, which is complicated by the varying prices charged and received for the coal, quantity and quality both entering into the subject. The bituminous output is consumed approximately in the following percentages: Railroads; 28; Industrials, 25; Coking, 15; Domestic, 10; Iron and Steel, 7; Public Utilities, 7; Export, 4; Mines, 2; Bunkers, 2.

The coal industry does not end at the mine. Some 180 railroads take the coal at the mine mouth and transport it to thousands of destinations. Because the railroads are the largest customers of the bituminous industry, and because coal—anthracite and bituminous—constitutes one-third of the railroad's freight the problems of the two are closely interwoven and their interests interdependent. Not only does irregularity in coal output mean serious fluctuations in revenue but excessive irregularity imposes impossible traffic demands on the railroads. On the other hand, interference with rail transportation means a corresponding stoppage of output for the mines and shortage of fuel for the consumer. No solution of the coal problem can be found that does not recognize this community of interest between coal and transportation. But this community of interest, though simply stated, is not simple upon examination. The movement of coal by rail and water is complicated by variations in freight rates, arbitrary differentials, and competition between different coals and between carriers.

Nor does the coal industry end with transportation. To connect the thousands of producers, big and little, with more than 90,000 buyers of carload lot coal scattered over

48 States, requires a widespread system of wholesale marketing. Sometimes this marketing is reduced to the simplest terms, as when a steel plant or railroad buys a mine and consumes its entire output. Sometimes it is conducted by the selling department of a large operating company. Sometimes the task of bringing together producer and consumer is performed by an independent wholesaler or selling agent. There are some hundreds of large wholesalers and a much greater number, perhaps 3,500 in all, of smaller middlemen. Like the business of running mines, the business of selling has its problems and, like mining, it has also its abuses.

The final link in the chain of coal supply is the retailer, who receives coal in carload lots from car or yard storage and delivers it in smaller quantities to the consumer. There are some 38,000 retail coal dealers, most of them conducting a small business. They handle about 130,000,000 tons of coal, or 14 per cent of the bituminous and two-thirds of the anthracite produced.

Combined charges of the railroad, the wholesaler, and the retailer in most localities exceed the price of the coal at the mines. Therefore it is readily seen that the problem whether the transportation and marketing charges are just and fair is of the utmost concern to the consumers of coal.

#### *Deficiencies in Service*

The widespread public dissatisfaction with the service rendered by the coal industry is not confined to matters of shortage and price, for a train of unfortunate consequences has followed those recurring periods of scarcity; deterioration in the quality of fuel delivered; congestion of railway traffic, necessitating the neglect of other freight to give preference to coal, to the serious harm of other business; and breakdown of mutual confidence of producers and consumers of coal as expressed in the customary contractual relations.

How many there are we do not yet know, but there are certain mines which contract a part of their potential output, reserving the balance for spot coal. These operators guard themselves against car shortage by clauses which compel them to fill their contracts only in proportion to the relative car supply. So in recent years, when speculators with contracts could get only a partial supply of cars, say 60 per cent, they would use only that percentage of available cars for deliveries upon their contracts, while the other cars would be used for spot coal; that is, they prorate their contracts with the sole purpose of having free coal for a higher spot market.

The record of production and distribution of coal in recent years may be summed up in the word "instability," and this instability in the supply of one of the most fundamental of all raw materials has been an important cause in unsettling business and in delaying the return of normal times.

1. *Large Profits.* It has been suggested to us that one of the causes of high prices of coal is profiteering. There has been profiteering in the sense that grossly exorbitant profits have been taken at times by many operators, brokers, and retailers; profits that have been disproportionate to the cost of the coal or the service rendered or the risk incurred.

But this Commission has not yet obtained the figures for the past ten-year period specifically required by the Act in order to settle this question. A thorough examination of the profits of production and distribution, including the revenue derived from associated enterprises, is already under way.

2. *Labor Difficulties.* Others attribute the instability in the coal industry primarily to labor troubles.

There can be no doubt that two of the three periods of high prices since 1916 have been caused largely by labor

troubles. In the first period of scarcity—August, 1916 to March, 1918,—there were no strikes of consequence and therefore some other explanation of the high prices and distress must be found.

3. *Car Shortage.* An opinion commonly expressed before the Commission is that the primary cause of scarcity and high prices of coal is transportation deficiency.

There have been recurring periods of "car shortage," and such periods have generally been accompanied by high prices of coal. There are many other causes for the inadequacy of transportation beside the absence of cars, such as lack of motive power, congestion of yards, terminal facilities, or gateways, single tracks where double tracks are needed, inability to co-ordinate movement of boats and cars at ports, strikes of railway labor, and severe winter storms temporarily blocking traffic. Any of these elements may be responsible for what to the operator at a mine seems a simple "shortage of cars."

4. *Overdevelopment.* Already in our study we have come to see that underlying these immediate causes of scarcity and high prices—labor difficulties and transportation deficiency—are other causes; namely, the irregularity of demand and the overdevelopment of the mining industry. These basic factors apply directly only to bituminous coal but indirectly they affect anthracite as well, for anthracite is in competition with bituminous coal and the wage scale in the one industry is influenced by changes in the other.

We find that in the bituminous industry since 1890 the mines have averaged, over the country as a whole, only 213 days out of a possible working year of 308 days. These averages, of course, show nothing as to the relative earnings of individual miners or their individual opportunity to work. In 1920, a year of active demand, the average time worked was only 220 days, and in 1921, the year of depression, it dropped to 149 days, with many districts showing a figure much below this average. Over a long period comparatively little of the time lost has been on account of strikes and that in the years when there are no strikes the aggregate time lost from all causes is about as great as in those when strikes occur. In the twenty-three years over which the statistical record of strikes extends, the time lost because of strikes has averaged 9 days a year, or less than 10 per cent of the time lost for all causes combined.

The steady increase in the army of bituminous coal miners during the last four years, notwithstanding a lessened demand for their product is also a fact that stands out in the statistical records furnished the Commission by the U. S. Geological Survey. In 1918, the year of maximum coal output, when 579,000,000 tons were mined, 615,000 men were employed in the bituminous coal mines, nearly 622,000 the next year, over 639,000 in 1920, and in 1921, 663,000 mine workers were employed in producing about 416,000,000 tons. To get a year comparable in soft coal output with 1921 we have to go back to 1910, when 417,000,000 tons were mined, and it is significant that in that year less than 556,000 mine workers were employed—or about a million more tons of coal with 100,000 fewer miners.

This condition of overdevelopment in mines and of surplus number of miners is an underlying cause of the instability of the industry. It means unemployment and intermittent employment to the coal miner and a direct loss of him of earning power. It explains his need and demand for a day wage rate higher than the average for most other industries. It has also adversely affected the profits of the operator and imposed a burden on the consumer.

The seasonal character of coal movement is a serious handicap to the railroads in those districts where it is the rule. If the peak demands of the mines are to be met the carrier must provide equipment for which there is no use in the off-season.

5. *Coal Storage.* A preliminary survey indicates that much can be done to overcome irregular demand by encouraging the storage of coal, and the Commission cannot stress too strongly the great advantages of coal storage during the spring and summer for fall and winter use. This recommendation should apply to all consumers of coal—the railroads, the public utilities, the industries, and the home—and on the measure in which it may be adopted will largely depend the evenness of distribution and the cost of coal to the public during the season of heavy consumption. In addition, it will contribute to more continuous operation of the mines during the summer, distributing employment more evenly throughout the year, thus tending to stabilize the industry. Coal storage, generally adopted by the consumer, large and small, would benefit the carrier systems of the country by equalizing their load. It should have the effect of reducing the price of coal to the consumer.

\* \* \*

There can be no satisfactory agreement as to wage rates and no lasting peace between operators and men unless steadier employment can be provided. There can be no satisfactory solution of our transportation problem as long as the railroads are subjected to sudden peak loads of coal traffic at the season when the demands of agriculture and industry are at their height.

The Commission believes that the public interest in coal raises fundamental questions of the relation of this industry to the nation and of the degree to which private right must yield to public welfare. It may be that both private property in an exhaustible resource and labor in a public service industry must submit to certain modifications of their private rights, receiving in return certain guarantees and privileges not accorded to purely private business or persons in private employ.

#### SYNTHETIC KEROSENE FUEL.

The solution of still another industrial problem has been undertaken at the research laboratories of Carnegie Institute of Technology, Pittsburgh, in experiments to determine the relative efficiency of kerosenes and oxidized kerosenes as fuels.

In accordance with the policy of the Institute to link up its educational facilities with modern industry, the Department of Chemical Engineering has been conducting a series of tests to determine the relative merits of various oils as usable fuels. The completion of this important work should go a long way toward solving the problem of oil conservation, by the possible development of a new fuel.

According to a report by Dr. J. H. James, Head of the Department conducting the experiments, oxidized kerosenes cause less "knocking" tendencies than straight kerosene when used in a kerosene engine. The tests also showed that oxidized kerosenes have approximately the same power development as ordinary kerosene, in spite of the fact that their thermal value is one-eighth less. Dr. James attributes the efficiency of the oxidized kerosenes to the better "clean up" in the combustion of these partially oxidized fuels.

The success of the experimental work at Carnegie at this stage gives promise that oxidized kerosene, which is manufactured by catalytic oxidation from low-grade petroleum, may become a useful fuel in the future. Its properties may cause it to be used industrially in kerosene engines or blended with gasoline for use in gasoline engines. Although it has a somewhat lower fuel value than ordinary kerosene, one of the most favorable features of its effectiveness is that it undergoes much better combustion in the internal combustion engine.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**COBALT.**—During the month of December the Nipissing mined ore of an estimated net value of \$279,000 and shipped bullion of an estimated net value of \$262,000. Silver was valued at 65 cents per ounce. The low-grade mill treated 6,958 tons and the high-grade plant only treated 95 tons, as it was shut down on December 15th. for the annual clean-up. The refinery shipped 405,297 fine ounces of bullion. During the year 1922 production is estimated at 3,350,000 ounces, worth \$2,265,000, which is the largest annual production in the last four years. Production of cobalt metal amounted to 365,000 pounds. The shipments during the year amounted to 3,682,815 fine ounces of bullion, and 2,961 tons of residues, estimated to contain 181,470 ounces of silver and 398,000 pounds of cobalt. Underground development has been satisfactory and some new ore has been discovered.

During the month of November the Mining Corporation treated 8,687 tons and produced 92,215 ounces of silver. Costs at the mine were \$49,409. The company has recently located some small bodies of milling ore on the Farah property, which it has under lease. It is also understood that encouraging results have been met with on the Lightning River properties, which the Mining Corporation has had under option for some time. So far work has been confined to surface trenching, but diamond-drilling will be resorted to in an effort to prove the ore bodies.

During the week ending January 5th the O'Brien was the only shipper from Cobalt, with one car containing 64,000 pounds.

The Casey Mountain Operating Syndicate will rebuild the plant and buildings destroyed by the big fire last October. The property is close to the Casey Cobalt Mine, north of Lake Temiskaming, which had a large production.

A few days ago the McKinley-Darragh office and warehouse were completely destroyed by fire. The company will not re-build, as other buildings can be used. The company's production for 1922 amounted to approximately 300,000 ounces, and it is understood that a substantial profit was made. The year's operations have disclosed a larger tonnage of good milling rock than was expected.

The Colonial shaft is now down over 700 feet and the company expects to reach the required depth by the end of February. The Violet shaft, in the same neighborhood, is down 150 feet and good progress is being made.

**KIRKLAND.**—The most important mining news of the past several months is the announcement that the negotiations for the taking over of the Orr property by the Teck-Hughes have been finally concluded. Rumors of deals have been reported for the past couple of years, and when arrangements were finally concluded people were rather taken by surprise, as very little has been heard of the matter lately. It is proposed to increase the capital of the Teck-Hughes to \$5,000,000, and to issue 600,000 shares for the Orr property. The purchase of the Orr is important to the Teck-Hughes, because

the main vein of the Teck-Hughes crosses a corner of the former property. Considerable development was done on the Orr, and at the 400-foot level it is stated that a length of 400 feet of ore was developed and that reserves are in the neighborhood of \$2,000,000. The property consists of 9 claims, totalling 276 acres, of which 84 acres adjoin the Teck-Hughes on the south. The Orr Gold Mine, Limited, has a capital of 2,000,000 shares, of which C. A. Wettlaufer of Buffalo owned 1,019,334 shares and Hamilton B. Wills, 730,030 shares.

A break-down of the Bidgood compressor has resulted in a stoppage of work until repairs have been made. It is understood that to date the company has found three small ore-shoots, which are not of sufficient size to justify a mill.

On the Canadian Kirkland property lateral work has been started on the 400-foot level.

At the Kirkland Gold a new vein has been found on the 800-foot level and to date development has opened up an ore-shoot 175 feet in length, which runs between \$10.00 and \$12.00 over a commercial width. This new vein has been found some distance to the north of the main break, along which all the previous development has been carried on. The ore-body lies in the porphyry and crosscuts are now being driven on the 700-foot and 900-foot levels to determine the vertical extension of the ore.

**BOSTON CREEK.**—It is announced that a new vein has been cut on the 100-foot level of the Baldwin property, which shows high-grade ore in places. Drifting has been started and it is understood that encouraging results are being encountered.

To satisfy judgment secured against the Murray-Mogridge Mines, Limited, the properties of the company will be put up at sheriff's sale in New Liskeard on January 30th.

**PORCUPINE.**—A preliminary statement of the Dome for the year 1922 shows a production of \$4,160,000 from 368,000 tons, an average of \$11.28 a ton. This shows a very substantial increase over 1921, when the production amounted to \$2,240,000. During December 33,500 tons were treated, and a recovery of \$361,000 was made, an average of \$10.88 a ton.

The vein recently cut on the 733-foot level of the Vipond is showing a substantial body of ore. To date 100 feet of drifting has been done and the ore averages better than \$11.00 across a stoping width. On the 1000-foot level a crosscut is being driven north to intersect the extension of one of the Hollinger veins.

## BRITISH COLUMBIA

**CEDAR CREEK.**—Speaking before the Vancouver Island Prospectors' Association, J. D. Galloway, government mining engineer for the Cariboo and other northern provincial districts, said the Cedar Creek field, newly discovered, would yield largely next season if proper weather conditions were met with. He put the production of the past year from that section at \$100,000. This was recovered almost entirely by the use of rockers. Mining on three separate claims had by test shown values

in the pay gravel of from \$25 to \$600 per cubic yard. When news of the discovery was first circulated it was much exaggerated. Stories were told of nuggets being found in vast quantities, almost for the labour of picking them up, and how millions of dollar worth of gold were in sight. Many people had gone into the district, failed to find easy gold or to secure a claim showing pay, and had come out with the report that the field was a fake.

Mr. Galloway discussed the placer gold possibilities of the Cariboo generally. He said that keystone drill tests made recently by the government had proved the suitability of the field for dredging. The high-grade gravels had been pretty thoroughly worked by the old prospectors, but large quantities of low-grade material existed. The same held true of other old-time placer fields and he was convinced that within a short space of time several big dredging companies would be operating in various parts of the Province.

**PORTLAND CANAL.**—A five-foot shoot of high-grade ore has been uncovered on the Fish Mine of the American Mining & Milling Co. from which returns have been obtained of \$107 to the ton. Fish Creek is in the Salmon River Valley, Portland Canal District.

The Premier Gold Mining Co. is reported to have maintained an average output of 300 tons a day throughout the past year, making a total for the twelve months of approximately 110,000 tons. High-grade material is sent to the Tacoma Smelter, the medium to the Anyox Smelter, and the low is run through the company's concentrator at the mine. Since the commencement of its operation, the eleven-mile aerial tram has been giving entire satisfaction. A continuous run of ore-carriers has been necessary to keep the ore bunkers at Stewart clear. In order to facilitate this a new steamer has been put in commission. The Company has had approximately 250 men on its pay roll throughout the year. It is stated that, in addition to its original claims, it now owns, controls or is interested in some fifty or sixty claims in the Salmon River Valley.

**HAZELTON.**—J. F. Duthie, of Seattle Wn., who has been developing some claims situated on Hudson Bay Mountain, near Hazelton, seems satisfied with his interests. He states that, if present indications work out logically, there is a mine in the making that will make the Premier look small. The showings are said to be similar to some of the silver deposits of Nevada and Mr. Duthie can produce assays of ore taken from a high-grade vein running as high as \$507 to the ton. The property does not depend on this, however, there being some low-grade veins giving returns of about \$15 to the ton. The high-grade ore is described as being rather like that of the Premier Mine, but without gold values. The values are said to increase with depth instead of pinching out as had been prophesied. The property is situated on the mountain-side about 1900 feet above the town of Smithers. A survey of the route for an aerial tramway to carry the ore to the railway has been completed and the construction work will start soon. Several carloads of ore have been sent to the Trail Smelter.

**OPTIMISTIC VIEW OF 1923.**—Valentine Quinn, controller of the Granby Consolidated Mining & Smelting Co., is quoted in an optimistic vein with reference to the prospects for mining development in British Columbia during 1923. "While much of the development work is under cover at present and it is, therefore, taboo to discuss it", he says, "it is now beyond doubt that the coming season will prove to be one of unexampled prosperity and development throughout the vast areas of this

province will proceed apace. From the coal fields of Fernie; from Trail, with its 2500 employees and its \$13,000,000 yearly output; from the Nelson District; and from Hedley and Princeton in the interior; Britannia Beach, Cariboo, Vancouver Island, Surf Inlet, Anyox, Stewart and the new mining areas contiguous to the Canadian Northern Ry., come reports of continuation, resumption and expansion of operations. Larger quantities of supplies will be required, more men will be engaged, and more extensive construction operations will be carried on in the mining industry than for a long time past."

**1922 RECORD FOR TRAIL SMELTER.**—A production of lead, which is over double the lead values produced in any previous year, is one of the features of the work of the Trail Smelter, Consolidated Mining & Smelting Co., during 1922. The smelter's output has climbed in quantity from 26,000,000 pounds in 1920 to 84,000,000 pounds in 1922, more than trebling within two years. Another noteworthy fact is that zinc production at Trail has increased in value over \$500,000. Silver, too, has increased 63 per cent in quantity and over \$500,000 in value. Notwithstanding that the production of gold and copper by the Company has sunk to negligible quantities through the closing down of the Rossland Mines and of the copper plant at Trail, the total value of metals produced for 1922 is 33 per cent. better than 1921 and 24 per cent. higher than that for 1920.

Final statistic of ore receipts at the Trail Smelter during the past year show that the total for 1921 was exceeded by 115 tons. During the last ten days of the month of December 11,343 tons were received. As the tonnage for 1921 was the largest for any year in the Company's history up to that time, the aggregate for 1922 creates a new record. A tonnage of 30,334 from custom mines, against 9,480 during 1921, strikingly tells the story of the renewed activity of independent operators. Of 50 shipping mines of the Slocan, including Ainsworth district, the Silversmith was the leader with 6831 tons of lead and zinc concentrate. The Standard at Silverton shipped 2496 tons, principally zinc, and the Bosun, at New Denver, 1240 tons. Five Washington State mines also went into four figures in point of ore shipments.

The tonnage of the Consolidated Company's properties dropped in 1922, as compared with the previous year, from 402,132 to 381,393 tons. This is due to the copper properties having been closed down until the new concentrator at Kimberley is constructed. The Sullivan Mine, of course, is the large shipper of the Kootenays.

#### UNITED STATES OUTPUT OF COPPER INCREASES IN 1922.

The smelter production of copper in 1922, according to the United States Geological Survey, as compiled from reports of the smelters covering the actual production for 11 months and the estimated production in December, was about 981,000,000 pounds, an increase of 475,000,000 pounds over 1921. Productive work was resumed by practically all the large mining companies except the United Verde Copper Co. by or during April, 1922, one year from the general shutdown of the copper mines. The smelter production of copper for December, as estimated by the producing companies, was 103,300,000 pounds, or at the rate of about 1,240,000,000 pounds a year.

The total production of new refined copper from domestic sources, determined in the same manner as the

smelter production was about 897,000,000 pounds, 88,000,000 pounds more than in 1921. The refinery production of new copper obtained from domestic and foreign sources, including the imports of refined copper, was about 1,328,000,000 pounds. In addition to the output of new refined copper about 112,000,000 pounds of secondary copper was produced at the refineries, making the total output of the refineries about 1,500,000,000 pounds.

Although the new tariff act placed no duty on copper, it affected the records of the Department of Commerce, in which a line of division was drawn on September 21, when the new tariff became effective. Up to that date the total imports of copper in ore, concentrates, matte, blister, and refined copper amounted to 309,445,226 pounds, of which 75,556,317 pounds was refined copper and 192,050,397 pounds was blister copper. The exports for the first ten months amounted to 634,501,851 pounds. The figures for later imports will not be available until January 15, 1923, but those for later exports will be available somewhat sooner.

The stocks of refined copper in the hands of domestic refineries on December 31, 1922, as estimated by the refining companies, were about 277,000,000 pounds, compared with 459,000,000 pounds on December 31, 1921. The stocks of blister copper and material in process of refining, in the hands of the smelters, in transit to refineries, and at refineries, on December 31, 1922, were estimated by refining and smelting companies at about 352,000,000 pounds, compared with 283,000,000 pounds on December 31, 1921.

The quantity of primary refined copper withdrawn on domestic account during the year was about 882,000,000 pounds, calculated as follows:

|                                                                                                                                         | 1921          | 1922          |
|-----------------------------------------------------------------------------------------------------------------------------------------|---------------|---------------|
| Refinery production from domestic sources                                                                                               | 609,000,000   | 897,000,000   |
| Refinery production from foreign sources, including estimated imports of refined copper                                                 | 411,000,000   | 501,000,000   |
| Stocks of new refined copper Jan. 1                                                                                                     | 659,000,000   | 459,000,000   |
|                                                                                                                                         | 1,679,000,000 | 1,857,000,000 |
| Exports, including unrefined black blister and converter copper in bars, pigs, and other forms, and refined in ingots, bars, rods, etc. | 609,000,000   | 698,000,000   |
| Stocks December 31                                                                                                                      | 459,000,000   | 277,000,000   |
|                                                                                                                                         | 1,068,000,000 | 975,000,000   |
| Total withdrawn on domestic account                                                                                                     | 611,000,000   | 882,000,000   |

Canadian water-power is a potent factor in metallurgical industry for the manufacture of aluminum, phosphorus, calcium carbide, carborundum, cyanamid, caustic soda, chlorine, sodium, chlorate, and artificial graphite, to mention some of its products. It is used to a large extent to supply power for mining and refineries whilst its prospective use for smelting and synthetic fertilizers promises an even wider field.

According to the New York World, eight hundred and seventy-five million fine ounces of gold, valued at \$18,000,000,000, have been produced by the world since Columbus discovered America. About \$8,000,000,000 is in circulation as money or in the banks and public treasuries of the world, \$2,000,000,000 of which is in the United States Treasury. The other \$10,000,000,000 worth of gold has been used up in the industrial arts or has disappeared in the 430 years since the keeping of accurate gold statistics began.

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

THOS. W. GIBSON,  
Deputy Minister of Mines.  
TORONTO, CANADA.

# BRITISH EMPIRE STEEL

CORPORATION LIMITED

CANADA CEMENT BUILDING

MONTREAL, CANADA

# PROVINCE OF QUEBEC MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

## Diamond Drilling for Oil

For wild-catting structure testing or production drilling,  
select SULLIVAN DIAMOND DRILLS

THE THIRD WELL

Completed by a diamond drill in the Tampico field was brought in July 1 at 1950 ft., with 800 bbls. flow. The Sullivan "P-2" drill completed this well in 29 working days.

### Advantages of the SULLIVAN DIAMOND DRILL for Oil Drilling

1. *Accurate records.* Exact knowledge of underground conditions is secured by means of the core.
2. *Drilling speed.* The Sullivan diamond drill is more rapid than either the standard or rotary rigs.
3. *Portability.* Sullivan diamond drill outfits are much lighter and more compact than other types.
4. *Two drills in one.* The Sullivan diamond drill operates satisfactorily in both hard and soft formations, and employs mud fluid if necessary, thus doing the work of both standard and rotary rigs.
5. *Size of hole.* The Sullivan diamond drill can bore a smaller hole than either standard or rotary rigs.
6. *Pressure Control.* Patented devices enable the Sullivan diamond drill to closely control the rate of advance of the bit, to continue drilling against heavy oil and gas pressures, and to remove the stem or rods without damage to the tools or rig.
7. *Lower cost.* Due to the consideration mentioned above, the cost of oil drilling with the Sullivan diamond is materially less than by any other method.

## Mining Engineer

The usefulness of a bank can only be judged by the advantages its service affords you.

The Imperial Bank, having over 200 branches distributed throughout the length and breadth of the Dominion—some of them located at remote points—is in a position to serve the mining engineer in all things financial. You will find this Bank's service always near at hand.

At all branches of this Bank the same courteous service is afforded to depositors whether their account be large or small.

*If judicious men skilled in chymical affairs shall once agree to write clearly and plainly of them, and thereby keep men from being stunned, as it were, or impressed upon by dark and empty words; 'tis to be hoped that these men [writers of vain books] finding that they can no longer write impertinently and absurdly . . . . . will be reduced either to write nothing, or books that may teach us something, . . . . . and so . . . . . we shall either by their books receive an advantage, or by their silence escape an inconvenience. —Robert Boyle, in "The Skeptical Chymist" — 1680.*

### A NEED, AND AN OPPORTUNITY

In the chain of events that leads on to the operation of a mine in Canada, there is a missing link. A fortune awaits the man who will forge that link.

Our mining industry is now well equipped with engineers, capable of the wise and economical direction of mining operations and conversant not only with the economic principles they must observe in order to make the most of their enterprises, but likewise with the special difficulties that beset the path of the miner. The operation of our mines can safely be left in their hands.

There is now a considerable number of mining engineers and economic geologists specially experienced in the initial development of prospects. It requires vision beyond the ordinary and a specially trained judgment to perform successfully and economically this important function in the making of a mine. Money must not be wasted, yet no reasonable chance of disclosing the pay-shoots must be left unexplored. It is said of the engineer whose acumen resulted in the discovery of the bonanza ore of the Premier that he is a "wizard"; the development of most prospects requires a certain amount of this wizardry.

In numerous mining districts across the Dominion, our prospectors are disclosing promising "showings" quite as rapidly as they can be taken up and developed. So much of our mineral-bearing territory is still completely unexplored, and such a large part of what has been run over in a preliminary way requires intensive prospecting, that prospects are sure to be discovered in large numbers for many years to come. Our growing mining industry is providing both the incentive and the means for a constantly increasing number of competent prospectors.

A number of our principal mineral-bearing areas are well served with railways. In fact the over-expansion of our railways has been to a large extent into mineral areas that have failed so far to provide the traffic anticipated. Almost without exception these

areas promise a good return to the prospector who will do faithful and discriminating work and to the engineer who will develop the "finds."

It is in the realm of finance that there is a need, and an opportunity. We have today, and shall always need, the little bands of adventurers who will expend their time or their spare cash on prospecting or on grubstaking a prospector. We have likewise a rapidly growing number of the syndicates formed with the object of developing prospects into near-mines. We shall need many more of these syndicates as the years progress, and there is every indication that their number will meet the need. There are also the organizations through which established mining corporations seek to re-invest part of their profits in the industry.

What our mining industry needs most just now is capital, in large amounts. We are getting a certain amount from investors in the United States, and a lesser amount from Britain. We can, and should, get very large amounts from the Canadian public. The inherent attractiveness of mining investment is such that it compels the attention of thousands of people who would not dream of speculative investment in any other field. At present the money of these people is withheld from the mining field. Why? Because there is at present available no agency for mining investment that will assure them both of scrupulous dealing and of discriminating expenditure. The investing public do not require a guaranteed return from a mining investment; all they want is a square deal and a good run for their money.

The man who fills this bill will not only do the mining industry and the country a service of first-rate importance, but he will earn a fortune. The public will entrust him with vast sums of money, and he will expend it wisely and profitably, with the aid of skilled engineers. He will do for the mining industry what others have done for, say, our water-powers; he will select promising near-mines and will provide them with the mining and milling equipment and the working capital necessary for profitable production. His

ventures will not always succeed; but on the average he will recoup his clients many-fold for their investment.

The Canadian mining industry, like Diogenes, is looking for an honest man.

#### CONFERENCE ON INDUSTRIAL RESEARCH

There is now in Canada a substantial and widespread interest in research. Up to the present, however, this interest has remained, in the main, unorganized and therefore ineffective. It was in an effort to consolidate this general interest by providing a definite objective and a means for its practical application that the Advisory Research Council at Ottawa proposed the establishing of a National Research Institute three years ago. Their attempt failed. No alternative solution has been provided, nor has any effective alternative been even suggested.

Meantime we are losing, every year and every month, the advantage conferred by a national institution to which each and every Canadian with an industrial problem to solve can come for advice, aid, and co-operation. It is true that the existing organization for research, notably those in our universities, are able and willing to aid industrial research in every way possible; but their limitations, which are obvious and have been the subject of much public discussion, prevent them from fulfilling the functions of a national institution. The fact that the universities, some of which were at first strongly opposed to the founding of a central institute for industrial research, are now uniformly in favour of it demonstrates their own realization of the need.

There is now renewed hope that the issue may be brought to a practical conclusion. Canadian manufacturers and boards of trade have, during the past three years, shown a surprising unanimity in favour of industrial research organized on comprehensive national lines. They lent their support, individually, to the Advisory Research Council's last attempt to found a National Research Institute, but it was not enough to ensure success. Now it seems that they are ready collectively to support the cause, and we can hope for a more fortunate result.

The Canadian Manufacturers' Association has arranged for a conference in Ottawa on February 20, 21 and 22 next, to which have been invited representatives of our universities. The Advisory Research Council will be represented; but (be it noted) the meeting has been arranged by the representatives of industry.

The leaders in Canadian industry have, during recent years, given indubitable evidence of their interest in industrial research. In many cases, unfortunately, this interest has not been crystallized in action, mainly

for lack of a compelling opportunity. We are confident that now they have tackled the problem officially, through their Association, they will find a solution—a safe, sound and sane solution—and will put it promptly into effect.

#### NEW WORK AT THE OLD MIKADO

An attempt is now in progress to operate once more the Mikado Mine, on the Lake of the Woods. Because this is a serious and honest attempt, and because a successful conclusion would mean so much to the discredited and abandoned gold districts of Northwestern Ontario, we have asked Colonel Machin to describe in the pages of the *Journal* the work he has in hand and his plans for the future.

The history of the gold fields of Lake of the Woods, the Seine river, Shebandowan, the Manitou and Wabigoon lakes, records a long series of excited adventures, wild speculations and stock-jobbing, with a rare example of an honest and enthusiastic, but misdirected, attempt at mine development. Many a likely prospect was ruined, not irretrievably but for many years to come. Numerous nice little mines were so saddled with debt and so involved in litigation that genuine mining operations were prevented. A few producing mines continued a precarious existence in spite of difficulties, but one by one they succumbed until the whole region was deserted.

The difficulties under which these properties struggled were, be it noted, mostly man-made. Nature had been fairly generous, if one can judge by the partial evidence disclosed. Dishonesty, greed, stupid management and ignorance were to a large extent responsible for the failures.

Though it is a well recognized fact that a discredited mining field is exceedingly difficult to re-open, however well authenticated its intrinsic merits, there are very, very few, who will act upon this knowledge. This is a curious phase of human nature, but still it is an undoubted fact. However, time has done much to clear the air in northwestern Ontario, and now it is possible to examine the facts in a fairly clear atmosphere. These facts are in many cases interesting and in a few cases promise well for the establishment of profitable gold mining.

It is difficult to interest mining men and mining investors in an abandoned field. Colonel Machin has been forced, therefore, to seek the co-operation of men whose eyes have not been thrown out of focus by gazing too intently at the misdirected efforts of former years. There is an element of danger in thus combining the efforts of men unaccustomed to the mining field; but it has the virtue of boldness, and there is no alternative.

We hope for much from the present venture at the Mikado mine. Though only partially explored, the

veins are very promising. Sufficient money has been raised to test out the property thoroughly. Colonel Machin's connection with the venture ensures the investors against stock jobbery or wilful waste of money. If competent direction is provided for the actual work of exploration and mining, the new Mikado may prove to be the pioneer in a northwestern Ontario highly production of gold bullion.

### BRITISH MONEY FOR CANADIAN MINES

A London financial journal, from which we print an extract on another page, gives some of the practical reasons why the British public have taken so little interest in Canadian gold mines. British investors are, in the main, shrewd and far-sighted, and since Canadian gold mines have now an inherent and well warranted attractiveness, there must assuredly be a good and sufficient reason why the British public is not investing in them to any substantial extent. The reasons may be summarised as follows:

It is difficult to buy and sell Canadian mining shares in London. They are not listed on any London exchange, and there are no local agents to receive and execute orders. There are no accredited London agents from whom information can be obtained from time to time. Our Canadian mining companies are not in the habit of publishing, month by month or quarter by quarter, detailed statements of the results of operations, as do the South African mines.

The British investing public are accustomed to these facilities, and until they or some satisfactory substitute have been provided it is not likely that Canadian mines will get their share of British capital. Provided these and similar conditions are met (and they can be met very simply) there is available in Britain a vast store of capital for the development of Canadian mines.

### EDITORIAL NOTES

The outspoken pronouncement of United Mine Workers headquarters at Indianapolis in reply to the request of a Nova Scotian "local" for a ruling on affiliation with the "red" organization in Moscow is good to hear. The handful of wild radicals in the colliery districts of Nova Scotia will find no substantial support either in Canada or in the United States.

The huge "porphyry" deposits of copper ore of the United States and Chile are at present the main sources of supply of the world's copper. They are worked profitably with a copper content as low as 1.5 per cent. On the outcrop it is very easy to overlook low-grade copper ore such as this, as it usually exhibits the green and blue copper stain only when the rock is broken into, and the iron gossan is ordinarily very sparse and

often almost unnoticeable. It is predicted by students of the metal market that the price of copper will reach a comparatively high level shortly and will remain there for years to come. It will be worth while for Canadian prospectors to keep a sharp eye for possible porphyry copper deposits.

A new gold prospect that appears to have considerable promise has been described, privately, to the *Journal* by the mining engineer who holds the right to dispose of it. The name and address of this engineer can be had on application by any who wish to look into the matter.

### HISTORY

#### II

O! They were some go-getters,  
These mining men of old;  
On earth are not their betters  
For action swift and bold.  
No socialists existed,  
Class-consciousness was not,  
And politics consisted  
In killing on the spot.  
These workers neozoic  
Had manners somewhat tough:  
They had to be heroic  
To call each other's bluff.  
No Workmen's Compensation  
Gave trouble to the boss,  
Or caused him perturbation,  
Or monetary loss.  
No worries did enmesh one,  
For if a miner died  
You simply got a fresh one,  
And let the matter slide.  
The dietary olden  
Included gruesome things,  
(Whose names shall be withholden)  
Like snakes equipped with wings.  
Large beasts they harshly whacked till  
They were entirely dead;  
They prized fresh pterodactyl  
And potted mammoth head.

\* \* \*

O! They were some go-getters,  
These mining men of old;  
On earth are not their betters  
For action swift and bold.

J. C. M.

[Editor's Note: — Some people have the mistaken notion that the poet's pay is "easy money". To any with this erroneous idea, we recommend an attempt to duplicate our own poet's rhyme for "pterodactyl."]

# Progress of Consolidated M. S. & P. Co.

SULLIVAN MINE AND CONCENTRATOR; INCREASED SMELTER CAPACITIES; NEW MACHINE SHOP AND FOUNDRY; PROSPECTS OF COPPER PRODUCTION

The construction of a concentrator at Kimberley, B.C., to treat the ores of the Sullivan Mine is the outstanding new work of the Consolidated Mining and Smelting Co., of Canada. This plant will have a capacity of between 1500 and 2500 tons a day. It will be of steel and concrete practically throughout. It will also be the last word in point of equipment in every detail. Some time during the early part of this year it will be ready for operation and its contribution to the economical handling of the ores of the Sullivan, one of the greatest lead-zinc properties on the continent, will form one of the most important of recent developments in connection with the mining industry of Western Canada.

The great objective is the saving of transportation costs. At present the ore as mined is shipped for treatment to the Trail Smelter. When its wheels begin revolving there will be shipped from the Sullivan the lead and zinc concentrates only. The result will be the release of the present thousand-ton mill at Trail for the handling of the production of the Rossland Mines owned by the Company.

Construction operations on the mill were started last spring, and the plant is about half completed now. In looking at the layout on the map, "Hill," "Tunnel," and "Concentrator" are at three points of a triangle. The "Hill" is the old portion of the mine, with its own connections and shipping facilities. The "Tunnel" is the portion of the mine worked through the big crosscut that was driven about three years ago, on the 3900-foot level. A raise from the Tunnel broke through into the Hill some 20 months ago, and the bulk of the ore will eventually come out through the lower level.

In preparation for the increased output, the movement of ore underground in the Tunnel has been re-organized by increasing the gauge of the electric railway to three feet and by installing 500-volt locomotives. These have to haul the ore from a point approximately two miles in. The mine has also been electrified throughout, and two new 3,000-cubic foot direct-connected air compressors have been installed, their location being at the Tunnel.

The ore from the Tunnel is dumped into a 900-ton receiving bin, from which it is fed into a 36 by 42 inch Buchanan jaw crusher, the product of which passes into two No. 8 Gates crushers. The product from this primary crushing is carried to a massive railway shipping bin holding 2500 tons, just completed.

To get the crushed ore from this point to the receiving bins at the concentrator, which is a couple of miles on the further side of Kimberley, a railway three miles long has been built. An incident of this railway is a trestle 1000 feet long and 53 feet maximum height, standing on piles, which was rushed up in 18 days. A line has also been built from Kimberley to the receiving bins. There is a third railway link, which connects the C. P. R. at a point below the site of the Taylor mill, with the concentrator's shipping bins. This

last line will be used both for shipping ore concentrates, and for bringing up coal for the boiler plant.

The great concentrator is over 700 feet long, down the slope, and 110 feet in width. Structural steel, with gunite — a concrete mixture blown from a gun — for the walls, and concrete footings, concrete floors, and concrete bases, are used, constituting of course the most permanent and indestructible type of construction. The roofs are as nearly fireproof as possible, with two-by-four lumber laid on edge, and a final covering of felt, tar and gravel. This same type of construction is used in all the new buildings.

When the plant finally commences operations, the crushed ore, arriving at the millsite, will first be weighed on 150-ton scales of the Fairbanks suspension type, and will then pass into a 1000-ton receiving bin, which has been blasted out of the rock. Conveyors will feed it into two 72 by 20-inch Garfield Alaska type rolls, arranged in series.

By means of other conveyors, the product from the rolls will be elevated and distributed into a 2500-ton receiving bin of massive proportions which is a sort of cupola above the concentrator. Pulley feeders will then feed it into 8 by 48 Hardinge mills. The Hardinge will be used for fine grinding throughout the concentrator, and eight of them will be installed.

The remainder of the plant will exemplify the differential flotation principle, with the use of alkaline solutions, as applied in the process worked out at the experimental zinc mill at Trail, which for the last year or more has been successfully treating 1000 tons per day of the refractory Sullivan ore. For refractory qualities the Sullivan ore, which is composed of various iron, zinc and lead sulphides, very intimately mixed, with practically no rock gangue, is supposed to hold the world's championship; but the Consolidated's specialists have successfully charmed it, and high-grade concentrates of both lead and zinc are now made without trouble, with good recoveries of both metals.

In the big concentrator the flotation machines will be of a modified standard Minerals Separation type; that is to say, the basic principle of the Minerals Separation company's patent will be used. The process, however, is far advanced from that contemplated in the original design.

There is a point of special interest in connection with the thickening of the slimes from the flotation machines. While some of the products will be thickened in Dorr thickeners, others will be thickened in Genter thickeners. The Genter thickener has been largely developed at the Sullivan mill at Trail. It is very compact while having a very large capacity, and its initial cost is much less than that of the Dorr, which is not much more than a settling tank. Several of the Genter thickeners can be put in the space of one Dorr of the same capacity. It is really a combination of thickener and filter, the solution drawn off from the Genter thickeners having already gone through a filtering process.

All the pulp from the thickeners will be filtered by the American disk filter.

Storage will be provided for the stocking of several thousand tons of both zinc and lead cake from the filter.

The mill will be driven by electric power, using a 575-volt three-phase 60-cycle current.

A machine shop, 45 by 150 feet in ground plan, is a part of the new equipment.

With the exception of the motors and coarse crushing machinery required practically all the machinery that will be used in the Sullivan concentrator is being made in the Trail shops of the Consolidated.

A very important development of the year has been the new line-up with respect to power. A year ago it was the expectation that the developments at Kimberley would require an extension of the power development at Bonnington Falls, by the West Kootenay Power and Light company, a subsidiary of the Consolidated. This has not been necessary, and the power will be supplied by the East Kootenay Power Company, from its Bull river and Elk river developments. Between 5,000 and 6,000 horse-power will be used by the mine and mill between them.

#### *Increased Capacity of Lead and Zinc Plants*

The new mill, however, is not the only item of progressive activity in which the Consolidated has been engaged. At the Trail Smelter there has been a 66 per cent. increase in the capacity of the Lead Refinery, which now can handle 150 tons in place of its former capacity of 90 tons a day. The former figure was attained in October last. This move is partly anticipatory of increases in lead-zinc ores from the Sullivan following the completion of the Kimberley Mill and partly to provide for prospective heavier demands from the Slocan District. As lead and silver are intimately associated in the characteristic ores of this territory, corresponding enlargements have been made in the silver refinery.

The tonnage of the zinc plant — a plant built to make 70 tons of zinc a day — has been brought up to a daily maximum of 100 tons, by improvements in processes and by increased efficiency.

An addition of the year has been the custom zinc plant of 30 tons capacity, comprising a complete separate roasting and leaching plant, which started operation June 1. By means of this plant Trail has been able to give the Slocan shippers a rate that nets them \$18 a ton more on the normal Slocan ore than is quoted by Trail's nearest competitor.

#### *Large Machine Shop at Trail*

These extensive enlargements and improvements in the institution's treatment plants do not represent the sum of the improvements. Plants that represent convenience and economy, but do not in themselves have any part in the processes of ore treatment, refinement of crude metal, or manufacture of the refined product, have had important accretions. For example, the big machine shop has been greatly enlarged, being now one of the largest shops in the province. It contains, among other machinery, the largest lathe in Canada, a Bertram lathe, Canadian made. Between its centers a cylinder 10 feet in diameter and 17 feet long can be hung for machining, or, at the other extreme, a cylinder 20 feet in diameter and four feet long. A crane

will pick up a complete 8 by 48 Hardinge mill, and the lathe will handle it. The general idea of having this great shop is to have as much as possible of the machinery required by the company for its plants and for its mines, of home manufacture, and already great economies have been effected. All the machinery for the great Sullivan concentrator at Kimberley, with the exception of the electric motors and the primary crushers, is being built at Trail. A recent glimpse of the shop revealed 160 parts for as many cells of the Minerals Separation flotation plant lined up. It is said that an automobile or a locomotive could be turned out.

#### *Large New Foundry*

Another betterment is "the most modern foundry in the province," the construction of which was started in November, and which went into commission a few weeks ago. This building, of steel and concrete, is 70 by 96 feet in ground dimensions. Over one-half of it a five-ton electric travelling crane moves back and forth. The other half has a second storey providing space for a pattern shop and a pattern storage room. The foundry has two cupolas for melting the metal, and a core-drying oven. It will also include a brass foundry. As an instance of the type of construction used, the upper floor consists of two-by-six lumber laid on edge, with concrete where the cupolas pass through it.

#### *Rossland Mines to Resume Next Fall*

The company is not at present operating its Rossland mines, but is keeping them pumped out, and in shape for resumption of operations. It is concentrating its efforts at present on getting in shape to mill the Sullivan ore at Kimberley, and the Rossland ore at Trail. When the Kimberley concentrator, now under construction, starts up next fall or perhaps at mid-summer, its operation will release for other uses the mill, now crushing 1000 tons of Sullivan ore a day, which has been used for the Sullivan experimentation. Until it shall have been shown that a larger mill than this will be justified in the interests of economy, the Rossland output will be handled by this mill. The much talked of Rossland concentrator will not be proceeded with at present.

#### *Copper Mines and Plants Idle*

During the depression of 1920-21, when so many smelters throughout the continent closed down, Trail still operated, and in 1921 actually increased the scale of its operations; but the company drew in its horns somewhat on mining, dropping development operation in numerous scattered mines about the province, and concentrating on production from its main properties.

At the present time none of its copper properties are being operated. The copper smelter and copper refinery are shut down. It is improbable that they will resume operation before the Rossland mines re-open, which will be when the Trail mill becomes available after it ceases to be required for the Sullivan ore. There is the possibility, of course, that the Canada Copper corporation may start up the Copper Mountain property earlier than that, in which case, of course, the copper plants would wait no longer.

The copper rod mill, specially built last year to take care of a substantial part of the output from the

greatly enlarged copper refinery, necessarily stands idle. It has never yet been operated.

#### Metal Prices

Markets during the year have been generally satisfactory, the net price movement having been upward. The price of zinc has risen about 40 per cent. and the price of lead is up about 20 per cent. Copper is also rising, leading to the hope that the mining of this ore may soon be attractive once more. On the other hand, silver is down materially.

A reflex of the increase in the price of metals is that the company's employees who are on a wage basis get a metal bonus of 60 cents a day. With the first war bonus of 50 cents still in effect they are now getting \$1.10 a day over pre-war wages. The staff also participate with an equivalent bonus.

The company at present has 1200 men working at Tadanac, 50 or 60 at Rossland, and 700 at Kimberley at the mine and on the construction of the mill.

All power for the company's plants at Tadanac and the Rossland mines is from the Bonnington plant of the West Kootenay Power & Light Company, its subsidiary. This big plant is now running up to full capacity, and there is hardly any doubt but that extensions will have to be made in the early future, as there is at the present time demand for more power than can be supplied.

One of the progressive steps just achieved is authorization by the legislature of the incorporation of Tadanac. This will bring all of Tadanac under one control. An arrangement is being negotiated whereby the city of Trail and the municipality of Tadanac will enjoy the advantages of consolidated schools, Trail maintaining the schools while Tadanac will contribute to their up-keep something over 50 per cent. of such expense.

It has been said that the Trail smelter is the keystone of mining in the Kootenay, and indeed of British Columbia. While proportionately less custom ore is treated at its plants than formerly, that is simply because the output of the Consolidated's own properties has increased out of proportion to the custom ore.

\* \* \*

In many respects the Trail smelter may be said to be the keystone of mining in Canada as a whole. It is unique in the world as assembling in one group a copper-gold smelter, a silver-lead smelter, a zinc plant, a refinery for the precious metals, an electrolytic copper refinery, and an electrolytic zinc refinery, not to speak of plants concerned with manufactured metal products and important by-products.

#### LETTERS FROM READERS

##### *Industrial Research at Toronto University*

To the Editor

Canadian Mining Journal

Sir:—

Permit me to congratulate you on your persistent effort in the direction of emphasizing the importance of research. Of course there is a large amount of research work going on continually at our mines. What is most needed probably is recognition of this research, which

should be recognized as an important department in every mining organization of consequence.

Your editorial on the Fellowship for Asbestos Research in the issue of January 12th rather indicates that there is no institution for the carrying on of industrial research in Canada. All our universities are carrying on some research work, and some of it is distinctly industrial.

In the University of Toronto within the Faculty of Applied Science and Engineering there is a School of Engineering Research which has been in existence for several years now, and has turned out some very creditable work. The facilities are here, the spirit is here, some trained workers are here—all that is needed is more funds. Consolidated Asbestos, Limited, or other industrial organizations might well establish research fellowships in this School.

Toronto Ont.

H. E. T. Haultain

##### *Commerce and Business Studies at Queen's*

To the Editor

Canadian Mining Journal

Sir:—

My attention has been drawn to an editorial and news item in the *Canadian Mining Journal* for December 22nd. last, which describes the development of business courses in the Technical Engineering Schools of the United States.

I am writing merely to draw your attention to the calendar of courses in Commerce and Administration at Queen's in which there is a graduate option for engineers. You will be interested to know that we have found among practising engineers a very considerable regret that more business courses were not included in the curriculum. Though we have been unable, up to the present, to establish a business option in the Faculty of Applied Science, we have done the next best thing in providing a course of one year's duration for men who have taken an engineering degree in some recognized college. As you may surmise, this is merely a makeshift, as for the most part men do not wish to spend another year in addition to the regular four years. Our registration in these courses has therefore been small, but we trust that in the future more Commerce work may be given within the Engineering School itself. At the present time, one class of two hours a week throughout the entire year in Economics and Business is given to fourth year students, and on the whole I think the tendency is to increase that. As our venture in the Commerce work for engineers is the first attempt, so far as I know, in Canada, to meet this very definite need, I have taken the liberty of calling your attention to it.

Queen's University  
Kingston Ont.

W. A. Mackintosh

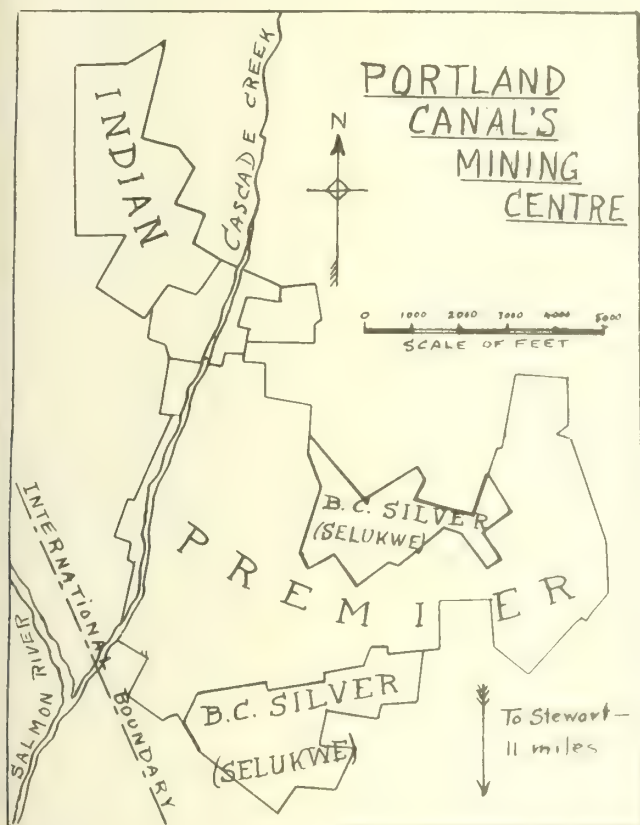

It is reported that all the coal properties and claims controlled by the late Lord Rhondda in Central British Columbia have passed into the hands of British interests organized for colonization work and for the development of natural resources in Western Canada. Some of these properties are situated north of the town of Terrace on the Grand Trunk Pacific Ry., about ninety miles east of the seaport of Prince Rupert. A market for the coal, which it is proposed to develop, may be obtained at Prince Rupert and it also is expected that an export trade to South America may be inaugurated.

# Buoyancy In British Columbia

By ALEXANDER GRAY

Not so long ago a well-informed British Columbia writer on the spot was within the facts when he stated that "another Premier Mine" had been diligently sought but had not been found. Such mines are not an every day occurrence, where structures vary and denudation has wrought havoc with mineral-bearing horizons. The Premier had to convince pioneers, and many of those who had clung to the Portland canal district, that the Bunting brothers and William Dilworth when they made their fortuitous trip in June, 1910, and staked eight Cascade Falls Claims, were in sight of the fortunes that went to Messrs Trites, Wood, Wilson and Neill, together with the Guggenheim interests, Keith, Untermeyer and others.

There was enough for all. The prospectors did not get it. After producing gold and silver to the value of approximately \$8,000,000 and disbursing \$3,100,000 in one year among its practically private owners—for it was not until recently the shares were introduced to the New York Curb — there is sufficient ore in sight to the 700-foot level to make the mine what its name signifies.

The position is so propitious that the owners have acquired other areas in the vicinity. Last year a proposal was made to the Selukwe Gold Mining and Finance Co. of London which controls the British Canadian Silver Mines Corporation, holding 902,000 of the 1,600,000 shares of five shillings each. As only 1,000,007 shares were issued up to a few months ago, the Selukwe Corporation was in absolute control of British Columbia Silver Mines, Ltd., which also holds interests north and south of the Premier, as well as in Bush mines and Salmon Bear River Mining Company Limited.

The Selukwe directors did not entertain the Premier proposal. They contemplated drilling. Really Sir E. H. Dunning is a weatherwise mining director, else he would not have been where he was at the Rand. He and his colleagues of the Selukwe board had not been fortunate in their Selukwe and Kafue-Rhodesian ventures, and they were well advised no doubt by C. A. Bank, M. Inst. M. M., domiciled at Vancouver.

Selukwe had been passive for ten years. Premier Company developments bestirred it, hence this London cable, bearing date January 17th.

A sensational feature on the mining exchange here yesterday was the rise in the 5 shilling shares of the Selukwe Gold Mining Finance Company from 8½ to 15½ shillings. This Rhodesian company also owns properties in British Columbia, and the sudden bound was due to a cable from Vancouver as follows: "Struck veins in crosscut. Large ore body. Undoubtedly main Premier Gold Mining Company vein. I consider it quite satisfactory. Future prospects excellent. Further information by cable later."

The Premier Company referred to in the cable owns adjoining property and is a highly prosperous concern. This cable resulted in a turnover of fully 70,000 shares. Last year these Selukwe shares changed hands at less than a shilling apiece.

If there is a Premier extension as intimated, the Portland Canal section between the Canadian Silver Corporation to and including the Indian Mines areas, now controlled by Montreal and Toronto interests, assumes greater importance. Possibly there is an interruption between the Premier and the Indian, in the Valley of Cascade Creek, but the Indian has the Premier elevation, is in the same horizon, and there is a series of veins with such values that the whole section becomes more than ever attractive. Further developments will be awaited by mining capitalists who understand what it requires to make mines in the Portland Canal district.

\*\*\*

Bearing upon this brief comment on what is transpiring in the Portland Canal country and further to the north, is a sentence that was buried at the end of a paragraph in the last issue of *The Canadian Mining Journal*. It reads:

"It is stated that, in addition to its original claims, it (the Premier Company) now owns, controls, or is interested in some fifty or sixty claims in the Salmon River Valley".

Hence the recurrence of the parable of the Wise and Foolish Virgins. Canadians in general have not known exactly whether Portland Canal is an adjunct to the British penal institution of that name, or is located near the place where they killed the dog for biting the wheel-barrow, in Milesia. Selukwe happened to place "A stack of whites" where a lucky card came out of the box, which already has made a difference of five or six million dollars to Selukwe shareholders, while Foolish Virgins hereabouts have slept or foreswore British Columbia. Yet Schofield, than whom there is no higher authority in the case, and Dr

Harron, have collaborated in a report based upon further investigations made two years or so ago, which substantiate this statement.

The geological conditions which surround the Premier mine, hundreds of miles north and south, along the eastern flank of the Coast Range batholith, and it is most probable that other properties similar to the Premier will be discovered in this large unprospected area.

Regardless of denudation and contentions regarding secondary enrichment, there are other mines in the *Journal*. The *Canadian Mining Journal* correspondent writes that the Wis. Virgins of the Premier Company have kept their lamps trimmed, in view of their increased holdings. Notwithstanding all of which, it is to be borne in mind that Portland Canal is no place for pienes or pink teas.

### PERSONAL AND GENERAL

C. H. MACNUTT has resigned from the superintendency of the Vimy Ridge mine of the Bennett-Martin Asbestos and Chrome Co., and now is with the Asbestos Corporation of Canada, Ltd., in charge of all their mining operations.

HUGH B. GILLIS, superintendent of iron ore mines and quarries for the British Empire Steel Corporation, was in Montreal last week at the head office of the Corporation on account of the virtual cessation of mining operations at Wabana consequent upon the French occupation of the Ruhr district. GEO. D. MACDOUGALL and F. W. GRAY, of the same company, were also in Montreal from Sydney, Nova Scotia.

J. B. TYRRELL addressed the American Association for the Advancement of Science, of which he is a vice-president, in Boston last month. His address, on "Mining in Canada", is published in "Science" of January 12th. It gives a concise, yet comprehensive, view of the history of Canada's various mineral districts, much of it from Mr. Tyrrell's own observation during his lifetime of work from coast to coast. The address concludes with a glimpse into the future of our mining industry, and the suggestion that here lies the field for a host of young men with a sufficiency of energy and ambition and a touch of the pioneering instinct.

MAJOR-GENERAL SIR A. C. MACDONNELL, Commandant of the Royal Military College, Kingston, addressed the Engineers' Society of Western Pennsylvania at Pittsburgh on Monday of this week.

G. C. BATEMAN, manager of La Rose Mines, Cobalt, is sinking the new shaft on the Violet property at a rate of about five feet a day which compares well with the records of the camp.

SIR ROBERT SQUIRES, premier of Newfoundland, is to visit Montreal this week in connection with the recent closing down of the iron ore mines of the British Empire Steel Corporation at Wabana.

M. F. FAIRLIE, manager of the Mining Corporation at Cobalt, has recently returned from a visit of inspection to the Corporation claims in the Lightning River gold area.

HARRY DONALDSON is to resume the direction of operations at the Beaver mine, Cobalt, now being reopened by the Coniagas.

FRASER D. REID, manager of the Coniagas, will act as consulting engineer for the Beaver.

The coal field in the vicinity of St. Georges, on the west coast of Newfoundland, has been sold to an Eng-

lish company, according to report. These seams of coal have been but little explored, but outcrops does not indicate that they will be of great importance. Heretofore coal from Nova Scotia has held the Newfoundland market. The new industrial undertakings on the Humber river, north of St. Georges, may stimulate the development of a local supply of coal even if from thin beds.

The price of lead in New York advanced last week from 7½ to 7¾ cents per pound.

Last year Ontario produced 7.2 per cent. of the world's supply of gold, coming next to the Rand. It is estimated that next year the proportion will be 10 per cent., or 30 million dollars.

U. M. W. A., Local No. 26, Sydney, Nova Scotia, has protested against the proposed importing of skilled coal miners. In the face of Mr. F. W. Gray's recent statement in the *Journal* that the reduced coal output of Nova Scotian mines is due principally to a shortage of skilled miners, this protest should not carry much weight.

The coal seams of New Brunswick are characteristically thin and hard to work, yet they are gradually being developed. Last year's production of 288,000 tons was the highest on record, and operators hope to maintain this gain.

New Brunswickers in Westmoreland county believe that a "blanket lease" held by the New Brunswick Petroleum Company over a large area of oil shale lands in the county is retarding development. They have therefore petitioned the local legislature that this lease be cancelled.

### INTERNATIONAL MINING EXHIBITION, LONDON

The 6th International Mining Exhibition will be held at the Royal Agricultural Hall in June under the Presidency of Sir John Cadman, K. C. M. G., and will be opened on June 1st by the Rt. Hon. Sir Philip Lloyd-Graeme, M. P., President of the Board of Trade.

The Exhibition has the support of all the leading Mining Institutions in Britain and abroad and is receiving widespread support from British firms. The Roumanian, Mexican and Columbian Governments have already taken space, and there will be comprehensive exhibits from France, Belgium, Holland, the Belgian Congo and Zambesia.

The Institution of Petroleum Technologists are organising a series of conferences and it is anticipated that there will be a large attendance of delegates from all parts of the world. Another interesting conference will deal with the question of "Safety in Mines" of which practical demonstrations will be given during the course of the Exhibition.

It is only a century ago since anthracite coal first came into use. At first it was found very difficult to burn, as the attempt was made to use it mixed, in various sizes, as with bituminous coal. It was not until after many years of trial that there was discovered the simple and effective expedient of screening it, when each of the various sizes burns without difficulty.

The French military occupation of the Ruhr coal basin has resulted in both French and German orders for British coal. Both these countries were drawing a very large supply from the Ruhr coal mines, and the interruption of their production, which threatens to be serious, will certainly benefit the British coal mines.

# The Mikado Mine

DESCRIPTION OF THE ATTEMPT NOW UNDER  
WAY TO OPERATE THIS WELL-KNOWN  
OLD PROPERTY ON LAKE OF  
THE WOODS

Many of the "Journal" readers will remember the mild excitement in Eastern Canada when in the nineties, and then spasmodically to within twelve years ago, gold was produced to possibly a total sum of three or four million dollars from the Lake of the Woods and adjoining districts. Gold mining then, to those few who were interested, was looked upon as a pure hit-or-miss gamble and the thought that the industry was really an ordinary commercial industrial enterprise, as fortunately it has become today, never occurred to them. Our people were accustomed to see fortunes made from timber operations, wheat speculations, etc., and looked upon these activities as safe and proper methods of accumulating wealth. Land speculation had preceded and then followed the spasmodic Ontario gold boom, then strictly confined to the Lake of the Woods and adjoining districts (for our Porcupine, Kirk and Lake and contiguous areas were then unknown); and although many fortunes were made from the lumber, wheat and land speculations gold mining was held to be a pure gambler's throw and was treated accordingly.

## *Business Methods Not Used*

That gold mining could be a legitimate commercial enterprise was then unthought of by our people. They had seen towns and cities built up by lumber, wheat and land booms and understood that situation, but they did not realize that towns and cities could owe their foundation and greatness to gold mining. They had not seen, for instance, San Francisco and Johannesburg, which were, among many others, founded, established and made beautiful by the product of the yellow metal as their staple industry.

What was the result? Shrewd business men who, if they had conducted their own successful businesses on the same lines as they conducted their gold mining ventures would soon have been penniless, took "a flyer" with the result that in most cases they lost, or if they gained it was as a result of stock gambling where their profits instead of coming out of the ground (as fortunately is the case with numerous Canadian gold mines today) came out of the pockets of the less fortunate and more gullible public.

Coupled with incompetence and in many cases even rank dishonesty, the gold mining industry in the Lake of the Woods was starved for capital. No serious effort was made to test the deposits at depth. Pocket-mining for high-grade was chiefly indulged in and quartz, and quartz alone, was supposed to be the sole depository of the precious metal.

It must be admitted, however, that the lack of modern mining and milling practice was a contributory cause to the non-success of early gold mining; but even that would have been overcome if cautious business methods, plus adequate capital, had been used as was ordinarily used in other commercial and industrial concerns. No! Gold mining was a simon-pure gamble and had to be treated as such.

The writer has been through it all, has made the same mistakes, and has paid bitterly in money and

heartache for his experience. But now cured? Never! Only more convinced than ever of the permanency and richness of the Lake of the Woods and Northwestern Ontario districts as potential gold producers, and this conviction arises from the knowledge gained in the hard school of experience.

Although anticipating my story, it may perhaps not be out of place as illustrating what I have just written to quote from a report of the Mikado Mine, which I have before me, made by Mr. W. E. Simpson, A.R.S.M.; M.I.M.M. dated from Swastika, Ontario, the 6th November 1922, as follows: — "Underground workings,

— The main vein, called No. 1, on which the greatest amount of work has been done, is almost vertical, but for some unaccountable reason the main working shaft was sunk at an angle of about 25 degrees, requiring some 1800 feet of cable on the hoist drum to raise the ore from a vertical depth of a little more than 400 feet. Possibly this shaft was intended to follow the pitch of the ore-shoot, but it must have been most costly and expensive to operate and, in addition to these disadvantages, it made the extraction of the ore immediately underneath a practical impossibility. Commercial success under conditions such as these could not be expected other than with ore of very great richness."

## *Financing the Present Operation*

The writer worked the Mikado Mine for some ten months nearly twelve years ago (when his money was lost and experience gained). All our efforts then were devoted to underground development work and to the proving up and blocking out of ore-bodies. We were forced to discontinue this work owing to lack of capital. In November, 1921, heartened by the wonderful development in Porcupine and Kirkland Lake and sure in the knowledge that these vein systems, with pay ore, had been proved to depth and realizing that similar geological features were present in the Lake of the Woods district, the writer once more tackled the operation of the Mikado Mine, sure in the knowledge that, given adequate capital, the Mikado would soon take its place amongst the steady gold-producers and dividend-payers of Northern Ontario.

The task was a hard one, for it was next to impossible to secure a sympathetic hearing from the investing public and the usual crop of "knockers" were (for reasons best known to themselves) much in evidence. However, the Mikado property, consisting of 278 acres freehold, plant and equipment, and options on certain adjoining freehold properties were purchased by and vested in the present company, Mikado Consolidated Mines, Limited, with its head office at 292 Imperial Building, Hamilton, Ontario. Sufficient capital being available, active work was undertaken at the mine in June last when a crew of men under Mr. Neil Morrison of Elk Lake, as superintendent, began the task of unwatering No. 1 vein, the present principal working, and cleaning up the mine. The work has proceeded without interruption until the time of writing, is still under way and will continue. At the time of the great fire in Northern Ontario, Mr.

Morris found it necessary to return to Elk Lake, and Mr. Dryden Smith, formerly of the Laurentian Mine (and others) succeeded him as superintendent.

#### *An Engineer's Report*

Later in October last the Directors secured the services of Mr. W. E. Simpson, A.R.S.M.; M.I.M.M. of Swastika, Ontario, to make an examination and report on the mine, so that it might be known what independent professional opinion of the venture was. The result was a long and favourable report, technical and full of detail, which is summed up in Mr. Simpson's own words in his final paragraph:

An examination of the Mikado Mine certainly gives a most favorable impression of its outlook and possibilities. The lowest levels, which in every mine are of greatest importance, here give the best promise of success. In keeping with the experience of all successful mines in Northern Ontario, the schisting and the industrial values tend to increase with depth. The 7th level is certainly better than the 4th, and reports indicate that the 9th, now under water, is better than the 7th. The past difficulty of operation is now being successfully overcome and the enterprise has a number of factors in its favor. Modern machinery and methods of treatment are highly efficient and with adequate financing and experienced management the future of the Mine can be considered as filled with expectations for industrial success. There is nothing spectacular about the ore but, what is infinitely better, the values exposed in the lower workings are what might be called industrially distributed. On the whole therefore, there is every indication that the property can be made to rank with the most successful gold mines of the country. Personally, I consider the mine possessed of excellent possibilities and have every confidence of its ultimate success."

The seventh level development spoken of by Mr. Simpson is the work formerly done by myself and associates twelve years ago and shows two ore-shoots 'one about 50 feet long giving an average assay value of about \$14.00 per ton for an average width of about 8 feet the other about 250 feet long assaying \$19.00 over an average of about 5 feet wide...Further...it would seem that the limit of length has not by any means been reached," to quote Mr. Simpson's report.

#### *The Present Mining Operations*

Following out Mr. Simpson's recommendations for future work on No. 1 vein, the original vertical shaft to a depth of 240 feet, abandoned by the original owners when they constructed the ridiculous incline shaft to take its place, has been re-collared, is being re-timbered, laddered, a new head-frame constructed and generally made ready for use to the 4th level at 240 feet vertical depth. A winze has been sunk in ore from the 4th to the 7th levels commencing at a point approximately 60 feet west from the incline shaft on the 4th level. This winze is vertical for some 80 feet, where it is continued to the 7th level at an angle towards the incline shaft and cuts the seventh level at roughly 240 feet from the incline shaft. This is now being fixed up with ladder-ways as an escapement. When the vertical shaft is completed to the 4th level, the incline shaft will be abandoned to that level. Opposite the vertical shaft in the fourth level and about 400 feet west of the incline shaft, a cross-cut some 20 feet in extent has been made into the hanging wall to cut the

vein. Here a winze has been sunk on the vein to within a few feet of a point where the prolongation of the seventh level drift westward for a distance of some fifty to sixty feet will intersect it. As this is all in ore, the foot-wall will then be cut to join up the vertical shaft to the seventh level and the incline shaft will then be completely abandoned as a working shaft and will only be used as an escapement.

The new vertical shaft to the 7th level and the 7th level itself will be the main artery of the mine until further development makes it necessary and economical to construct a large main working shaft elsewhere.

#### *Projected Development*

It is proposed to drive the 7th level westward until the junction has been made with the fourth level winze, provided the ore-body continues.

A winze will be sunk on the vein in the floor of the 7th level west, which is the deepest developed point. (360 feet vertical) in this portion of the mine, for 100 feet and the vertical shaft continued after the ore body has been proved, and this plan will be followed at this point as long as the vein continues to go down, which we believe will be to a considerable depth.

Cross-cuts on the fourth and seventh levels will be made in both walls to explore certain possibilities which heretofore have remained unexplored. Large bodies of mineralized Keewatin schists, lying next to porphyry dykes, have never been tested or sampled. This will be done systematically. Heretofore only the quartz itself was investigated. A very large tonnage of milling ore may become immediately available if it is proved that the mineralized schists carry profitable gold values.

Other development work has been tentatively projected but until the programme outlined above has been well advanced nothing further will be attempted.

At present there is estimated some half million dollars worth of ore either broken in the mine or blocked out and available for stoping when the mill is put in commission. Information from diamond-drill cores and other sources entitles me to say there is potentially (although not blocked out) a very large amount of ore in the vein system.

Only last week while on new work on the floor of the seventh level rich ore showing free gold was encountered, but while interesting to show that free gold still exists in the lowest workings reached in the mine, it is not what the writer is looking for or depending upon. Rather it is from the large bodies of \$10.00 ore, which we have already proved and are developing but which shows no visible gold, that we expect to make the dividends.

#### *The Milling Plant*

Mr. Simpson has made his report on and recommendations for the remodelling of our milling plant. His object has been to use as much of the old plant as is justifiable from an economic standpoint and to add to it only sufficient modern machinery to enable economical work being done. A ball-mill, Wilfley tables and partial re-modelling of the present cyanide plant is thought sufficient for the present to take care of a 60-ton daily production. The present stamps will be used for coarse crushing for the ball-mill. This plant will be placed in commission about 1st June next and from then on will be used until circumstances warrant

the addition of further units, which will be of an approved type and will be added from time to time as future development warrants.

The main object the management has in view at the present time is underground development, to block out ore reserves to such an extent that, no matter who measures and samples and re-measures and re-samples, the future permanency of the mine for many years of production is assured beyond all question of doubt.

The question of power has yet to be determined. For the moment, steam power from cord-wood is the power used. Modern engines have greatly reduced the fuel consumption and it is estimated that eight cords per day will now accomplish what formerly required twenty. But this is only a temporary measure and the coming summer will see the matter definitely settled, with either hydro-electric power from one of two sources already available, or electric power from oil fuel engines with direct drive (probably under the circumstances the most economical power available) or producer-gas engine.

The present directors are Lt.-Col. H. A. C. Machin, F.R.G.S. of Kenora, Ontario, President; Captain George J. Guy, of Hamilton, Ontario, Vice-President; Major George H. Marsh, of Toronto, Ontario, Secretary-Treasurer; and Messrs. Walter P. Thompson, of Hamilton; J. T. White, K.C., of Toronto, A. H. Dinning, of Detroit, Michigan, and J. C. Stevenson, of Toronto.

H. A. C. MACHIN.

Kenora, Ont.

## CANADIAN GOLD PRODUCTION

### *Reasons for Lack of Interest in London*

Except for Canada and the United States, the gold mining companies of most countries publish very full information as to the monthly working results in detail, many issue quarterly results as to the finances and particulars of the nature of the developments, and several of the more important companies issue maps and plans with their annual reports. Information is afforded by publication in the newspapers and frequently by issue of direct circulars, &c., to the individual shareholders. The great majority of companies have head or branch offices in London. In all this essential information Canada apparently restricts itself to publishing particulars in Canada. Though, it may be, the English shareholders get official reports, &c., the general public in this country is scantily informed as to progress and events, and the Press itself is left much in the cold as to receipt of official reports or announcements.

We are led to bring out these points as we understand there are complaints of difficulty in obtaining information as to the Canadian gold mines now producing in Ontario province. The Hollinger Mine has achieved a world-wide reputation for richness and extent of its ore deposits. Despite the fact that it has \$25,000,000 of capital, any inquiry for information has to be addressed, by persons in Europe, to the company's office in Bay Street, Toronto. Any investments by persons this side of the Atlantic are difficult to affect, and would-be speculative investors are disinclined to take the steps necessary for them to acquire an interest in a share in which there is no ready market here. Careful men want to be furnished with some

readily accessible means of obtaining information as to results being secured, &c.

We have intermittently in recent months called attention to the good discoveries made in the Ontario gold fields. The rate of production of gold is extending and companies are enlarging, or preparing to enlarge their reduction plants. Here, however, scant heed is given to the matter.—The Stock Exchange Gazette (London).

## NITRIC ACID MANUFACTURE IN CANADA

Canada is to have a new and somewhat unusual industry. Two years ago an American company established a small plant, costing approximately \$500,000 at Lake Buntzen, on the north arm of Burrard Inlet, near Vancouver for the extraction of nitrogen from the air by electricity. Two years of operation have proved the practicability and commercial profit of the scheme, and now the company plans an elaborate extension of the plant, at an expenditure of between \$3,000,000 and \$4,000,000, to take care of the production of nitric acid. There is stated to be only one other such plant on the North American continent.

The extension of the present plant for the manufacture of nitric acid has been forced on the company by the recent increase to 600 per cent. in the United States tariff on nitrate products used in making dyestuffs, paints, inks and films which the Buntzen Lake plant has been turning out. As the tariff shuts these products out of their chief market in the United States, nitric acid is to be manufactured, for which there is practically an unlimited market.

On account of the cheap power available it is claimed that the Canadian industry can manufacture nitrates cheaper than they can be imported from South America, which has hitherto been the principal source of supply. In the past fiscal year Canada found it necessary to import from other countries nitrate of soda to the extent of 22,838,208 pounds, worth \$581,907, nitric acid to the extent of 71,643 gallons, worth \$11,456, nitrate of ammonia, 2,017,078 pounds, worth \$127,484, and other nitrates to the extent of \$71,306.

There are immense possibilities to the industry of manufacturing nitrates from the air in Canada. Nitrates form a very important ingredient in fertilizing crops, and Norway utilizes over 300,000 horse-power in manufacturing nitrates in this manner and exports some 60,000 tons of fertilizer. Nitrates form the basic materials of other Canadian industries, and their absolute necessity in the manufacture of munitions is still an important national consideration. With Canada's unexcelled water-power resources the manufacture of nitrates from the air might become an industry of such proportions that the Dominion would take second place to no country in this regard.—From "Industrial and Agricultural Progress in Canada."

The Grass Valley gold field, in Nevada county, California, was during 1922 the most productive quartz-mining district in the state. Its veins are characteristically narrow, with high-grade ore-shoots. The Bridge River gold area, northwest of Lillooet, British Columbia, has been favourably compared with the Grass Valley field by Dr. W. S. McCann, of the Geological Survey, Ottawa. Another Canadian field that resembles it is the Mine Centre area in northwestern Ontario.

# A New Steel Company

ALLOY STEEL MANUFACTURE FROM  
CANADIAN ORES

At Welland, Ontario, there is to be in operation within a few weeks a new and important industry. The Welland Alloy Steel Corporation, Limited, is now actively engaged in preparing for manufacture on a large scale, and its plans envisage operations that will employ in the near distant future upwards of 2,000 men.

The new company has purchased the entire property and stocks of Electric Steel and Metals, Limited, which has been idle for the past two years. The property is on the bank of the Welland Ship Canal, with a frontage of 1300 feet and dockage capacity of the same length, and it will have as well the use of a large ship-turning basin when this shall have been completed by the Department of Public Works.

The highest grades of steel now made in any quantity are the product of the electric furnace. The new company has already in its plant two 7-ton Heroult electric furnaces, with a combined capacity of 30,000 tons a year. This capacity is to be increased to 45,000 tons a year by the addition of a third furnace. It is intended to instal during the present year a rolling plant to turn the ingots from these furnaces into the various shapes required in the trade.

Cheap power for metallurgical purposes is rapidly becoming a thing of the past in the Niagara district. Hence a contract held by the company for their supply of power at a very favourable rate is an important asset. This contract has 37 years still to run, the rate being from \$14.62 to \$15.82 per horsepower-year.

One of the Company's chief assets consists in deposits of nickel ore on the northern part of the Sudbury nickel range, lying between the Levaek Mine, the

Mond Nickel Company's principal ore-deposit, and the Whistle Mine, where the British America Nickel Corporation has a huge reserve of ore. Exploration has showed that the deposits now owned by the Welland Alloy Steel Corporation are high in nickel and low in copper, which suits exactly their purpose of making nickel alloy steel. As this part of the northern edge of the nickel range is not served at present by a railway, a charter has been obtained with liberal terms for the construction of the line needed to connect the end of the steel at Levaek Mine with the Canadian National line at or near Nickelton Junction. The work preliminary to the actual construction of this line has been completed.

The principal purpose of the Welland Alloy Steel Corporation is to manufacture nickel alloy steel from the ore of the Sudbury district, which contains in natural combination the iron and the nickel required for this purpose. The company owns the rights to a patented process whereby these two metals are reduced together direct from the ore, thus not only making use of the iron in the ore, which is usually wasted, but avoiding the expense of separating out the nickel. In the ordinary process of making nickel steel, the nickel is separated at great expense from the other constituents of the ore, refined, and then added to a bath of refined molten steel in the furnace. By means of the new patented process, the nickel and iron are separated together from the ore by a very simple means, the bath of combined metals is refined, and then any other alloying elements required, such as chromium, silicon or manganese, are added. Thus a direct process is

Plant of the Welland Alloy Steel Corporation, Welland, Ont.

substituted for the round-about process now in vogue, at a great saving in expense. The process has been tried out already very thoroughly in small-scale commercial production.

In addition to this special nickel steel it is proposed to manufacture high-grade plain carbon steels, all the products being obtainable from the works in rounds, squares, bars, angles and special shapes, as well as in ingots and billets.

The personnel of the new company's administration are men already thoroughly experienced in the steel industry, and well fitted to direct the new enterprise. They include the following:

G. F. Allerdice, first vice-president of the Brier Hill Steel Company, Youngstown, Ohio. This company operates blast-furnaces, open-hearths, coke plant, blooming mills, merchant mills and sheet mills. It owns its own coal mines and has a fleet of lake cargo boats for ore. It employs between five and six thousand men.

W. H. Devlin, who for twenty years was general superintendent of the Carnegie Mills, Sharon, Pa. This plant is owned by the United States Steel Corporation and employs upwards of 2,000 men.

H. William Sharpe, first vice-president of the Joliet Forge and Steel Company, of Joliet, Ill. The rolling mills and forge shops of this company are owned by the Sharpe family, and have accumulated for the owners a reserve fund of over one million dollars.

G. B. Nisbet, formerly Metallurgical Engineer for the Brier Hill Steel Company.

H. E. Timmerman, Welland, formerly engineer for the Ontario Hydro-Electric Commission.

J. Ferguson Black, Sudbury, mining engineer.

The active management of the company will be in the hands of Messrs. Devlin, Sharpe, Nisbet and Black.

With an ideal location, and a personnel notable for long and successful experience in the steel business, the Welland Alloy Steel Corporation, Limited, commences its operations under most auspicious circumstances.

## OIL FROM COAL

The waning petroleum supply of the country may be supplemented to great extent, according to Charles R. Fettke, Associate Professor of Geology and Mineralogy at Carnegie Institute of Technology, Pittsburgh, by taking the enormous quantities of bituminous coal now being burned in the raw state for steam raising purposes and domestic use, and subjecting it to low temperature carbonization. This process, he says will produce a fuel that is in many respects superior to raw coal, the smoke nuisance of cities will be abated, and valuable by-products will be recovered, which will aid greatly in augmenting a petroleum supply that is being rapidly depleted. Professor Fettke emphasizes the warning in his report, that the unmined reserves of petroleum are being so rapidly reduced that one of the problems that will have to be faced within the next decade or two will be to find substitutes in continually growing amounts for the products now obtained from it.

"The distillation of oils from oil shales, another important source of supply, will be restricted to those regions where enormous quantities of the shales are found," says Professor Fettke. "Where bituminous coal is found in larger quantities than shale, it will

be more economical to confine the business of oil distillation to coal.

"With the growing shortage of natural gas and anthracite coal and their consequent increase in price, other sources of domestic fuel must come more and more into use. One of these will undoubtedly be low-temperature coke. The low-temperature carbonization of coal in this respect will have the advantage of the oil shale industry. It will yield a valuable fuel as a residue while the spent shale from the latter not only has little or no economic value, but means will have to be provided for its disposal."

## AN AUSTRALIAN ASBESTOS QUARRY AND MILL

A small asbestos quarry and mill now operating in New South Wales, Australia, on Mount Fibro 11 miles east of Barraba, are described in the December issue of *Chemical Engineering and Mining Review*, Melbourne. The Asbestos Mining Company of Australia, Limited, was formed in 1918 to open up the deposits and has continued to operate since that time.

The asbestos fibre occurs in a belt of serpentine a quarter of a mile in width, and has been shown to be present throughout at least three-quarters of a mile of its length. White silky fibres are found in a network of seams in the serpentine, these seams being from  $\frac{1}{4}$  to  $1\frac{1}{2}$  inch in width, with an average of  $\frac{3}{4}$  inch. The fibre in these seams is usually divided by a line of parting, making them shorter than the full width. In places there is found a "ribbon" structure showing as many as 120 bands to the foot. Seams of magnesite occur characteristically with the seams of chrysotile asbestos.

The asbestos rock is quarried from an open pit, and over half is rejected as waste. The remainder is treated in a mill very similar to some in the Thetford, Quebec, asbestos area. It is crushed in a gyratory crusher, and then in rolls. A trommel removes material under 12-mesh, which is discarded.

The oversize, after drying, is reduced to one-eighth inch in rolls and again screened, on a shaking table covered with 9-mesh wire cloth. The undersize is discarded and the oversize treated in a Jenke's fibreizer, which is a cylinder 8 ft. long by 3 ft. in which revolves a shaft carrying 11 pairs of beaters rotating at 300 r.p.m. The beater arms are set diagonally, to carry the pulp forward to the discharge end. After the undersize (sand) is separated on shaking screens, the beaten fibre is collected by suction off shaking tables.

The amount of fibre recovered is 5.75 per cent.

The mineral production of Utah increased from \$22,023,000 in 1921 to \$39,738,000 in 1922. There was a record production of silver, 16,800,000 ounces, an increase of more than 4,500,000 over 1921. Copper produced in 1922 was 95,500,000 pounds valued at \$12,797,000, against 30,891,000 pounds worth \$3,985,000 in 1921. The Utah Copper Co., produced over 10,000,000 pounds a month during the third quarter of the year, which is about half its maximum capacity.

Australia imports from £6,000,000 to £8,000,000 worth of fuel oil annually. This has stimulated a very active search for oil throughout the Commonwealth, which has been so far unsuccessful.

## IRON ORE PRODUCED IN UNITED STATES IN 1922

### INCREASE IN OUTPUT AND VALUE

The iron ore mined in the United States in 1922, exclusive of ore that contained more than 5.5 per cent. of manganese, is estimated at 46,963,000 gross tons, an increase of 60 per cent. as compared with that mined in 1921. The ore shipped from the mines in 1922 is estimated at 50,046,000 gross tons, valued at \$158,222,000, an increase of 88 per cent. in quantity and of 76 per cent. in value as compared with the figures for 1921. The average value of the ore per gross ton at the mines in 1922 is estimated at \$3.16; in 1921 it was \$3.37. The stocks of iron ore at the mines, mainly in Michigan and Minnesota, apparently decreased from 13,836,267 gross tons in 1921 to 10,699,000 tons in 1922, or 23 per cent.

These estimates, which are based on preliminary figures furnished by producers of 98 per cent. of the normal output of iron ore, were made by Hubert W. Davis, of the United States Geological Survey, Department of the Interior. They show the totals for the principal iron-ore producing States, and, by grouping together certain States, the totals for the Lake Superior district and for groups of southeastern and northeastern States.

### Lake Superior District

About 86 per cent. of the iron ore shipped in 1922 came from the Lake Superior district, in which 39,602,000 gross tons was mined and 43,095,000 tons was shipped, increases of about 58 and 89 per cent. respectively, as compared with the quantities mined and shipped in 1921. The ore shipped in 1922 was valued at \$145,150,000, an increase of about 78 per cent. These totals include the ore mined and shipped from the Mayville and the Baraboo mines in Wisconsin and ore shipped by rail as well as by water from all mines, but exclude manganese ores that contained more than 5.5 per cent. manganese. The ore is chiefly hematite. The stocks of iron ore in this district apparently decreased from 12,574,457 gross tons in 1921 to about 9,034,000 tons in 1922, or 28 per cent. The shipments of iron ore by water from the Lake Superior district in 1922 (including manganese iron ore), according to figures compiled by the Lake Superior Iron Ore Association, amounted to 42,613,184 gross tons, an increase of 91 per cent. as compared with these shipments in 1921. The average value of the ore at the mines in the Lake Superior district in 1922 per gross ton was \$3.75; in 1921 it was \$3.58.

The mines in Minnesota furnished 70 per cent. of the total iron ore shipped from the Lake Superior district in 1922 and 60 per cent. of the total of the United States. The mines in Michigan furnished 29 per cent. of the Lake shipments and 25 per cent. of the grand total.

### Southeastern States

The Southeastern States, which constitute the second largest iron-ore producing area, including the Birmingham and Chattanooga districts, mined 5,384,000 gross tons of iron ore in 1922, an increase of 80 per cent. as compared with 1921. The shipments of ore from these States to blast furnaces in 1922 amounted to 5,372,000 gross tons, valued at \$9,901,000, an increase in quantity of 84 per cent. and in value of 85 per cent. as compared with the quantity and value of shipments in the previous year. The ore contains about 78 per cent. of hematite, 21 per cent. of brown ore, and 1 per cent. of magnetite. The average value of the ore in these States in 1922 per gross ton was \$1.84; in 1921 it was \$1.83.

### Northeastern States

The Northeastern States, which include New Jersey, New York, and Pennsylvania, in 1922 mined 1,413,000 gross tons of iron ore and shipped 1,015,000 gross tons, an increase of 109 per cent. in the quantity mined and of 113 per cent. in the quantity shipped in 1921. The average value of the ore in these States in 1922 per gross ton was \$2.03; in 1921 it was \$3.75. Most of this ore is magnetite.

### Imports and Exports

The imports of iron ore from January 1 to September 21, 1922, amounted to 684,387 gross tons, valued at \$2,894,496, or \$4.23 a ton. The imports for the year 1921 were 315,768 gross tons valued at \$1,075,909 or \$3.41 a ton. The exports of iron ore for the eleven months ending November 30, 1922, amounted to 602,095 tons, valued at \$2,770,160, or \$4.60 a ton, as compared with exports for the entire year 1921 of 440,106 tons, valued at \$2,077,620, or \$4.72 a ton.

### Pig Iron

The production in 1922 of coke and anthracite pig iron and blast-furnace ferroalloys, according to the Iron Age, was 26,880,383 gross tons, an increase of 62 per cent. over the output in 1921, which was 16,543,686 gross tons.

In speaking recently of the world's unexploited resources of petroleum, Sir John Cadman drew attention to the facts that Mexico's huge production has come from a narrow strip of land along the coast, whereas most of the interior is underlain by petroliferous measures; that the output of the United States is still increasing; that "cracking" methods are making possible a higher yield of motor spirit, and will probably be much further improved; that certain old fields will renew their youth and that many new fields will be found; and that soon coal will be made to yield its oil before being burned.

In 1914 Sir William Ramsay suggested that coal should be gasified underground, without removing it from the seams, and the gaseous fuel conducted to the surface. Experiments made recently in Italy on a bed of lignite serve to indicate that, at least with coal of this quality, the method has some chances of practical success.

It is reported in Sydney, Nova Scotia, that negotiations for a schooner to take an expedition to the Labrador "gold fields" early in February are being conducted here by an agent acting on behalf of a company of Glace Bay adventurers. Sydney men are also planning trips to Stag Bay, but they have no intention of setting out for the rock-ribbed coast before July 1st.

With the record of being one of the two copper companies in the British Empire which kept in operation following the after war slump, the Granby Consolidated Mining and Smelting and Power Company at Anyox, B.C. is now preparing for an extensive addition to the present plant. Construction has already started on one of the largest multiple arch storage dams on the American continent to provide them with a storage dam for power purposes. The new dam is costing approximately \$500,000, and when completed will take care of 32,000 acre-feet of water.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS.

## NORTHERN ONTARIO

**POWER FOR HOLLINGER.**—Hollinger representatives are again meeting officials of the Government in order to take up the question of power development on the Abitibi River, and to see just what terms the Hollinger can obtain. The most important point in dispute seems to be the fact that the Abitibi Power & Paper Company, who have made extensive improvements on the river, only use the water six days a week, while the Hollinger wishes to develop power for the full seven days. The Abitibi Company has made large expenditures in improving the river and developing its own power, and has added to the value of developments lower down the river. The company claims it should be given consideration on account of the improvements made and also because of its intention to expand its plants. The Hollinger, however, wants power rights free of any encumbrance. The Northern Canada Power Company has presented a memorandum to the Government, stating that the Government should not interfere between litigants. The appeal of the Hollinger against the decision in its suit for damages is still pending, as is also the Northern Canada Power Company's action to have the Hollinger sign a contract for all its power requirements.

**SPECTACULAR SHOWING AT KEELEY.**—In the No. 26 vein to the Keeley Mine in South Lorrain, the most spectacular discovery of silver ore ever seen in this country was recently made. The present face shows a width of 5 feet of solid ore across the top of the drift and 4 feet at the bottom, and it is stated that the ore runs approximately 7000 ounces to the ton. The face will not be disturbed until officials of the Bureau of Mines have had an opportunity of photographing it. The recent estimate of 1,500,000 ounces in reserve at the Keeley is already out of date, as this figure has been greatly exceeded. Production for 1922 amounted to 770,000 ounces, as compared with 313,000 for 8 months of 1921. Production in December was 79,000 ounces, but on account of this last big discovery January, no doubt, will be very much higher.

**ROUYN GOLD PROSPECTS.**—Companies operating in the Township of Rouyn, Quebec, are preparing to bring in machinery over the recently completed winter road. Cockeram claims, which are under option to Jack Hammel and associates, will be diamond drilled, and the contract has already been let. Two drills will be sent in shortly. The Thomson-Chadbourne syndicate is bringing in a mining plant to start sinking on the Powell claim. It is stated that on this claim one section of the vein has been opened up for a length of 400 feet, and averages \$12.00 over a width of 6 feet. This syndicate has recently made a payment of \$7,000 on the Miller-Horne group, and controls a length of about two miles on the vein.

**BRANCH RAILWAY SURVEY.**—T. & N. O. engineers have commenced to survey the projected branch line from Swastika through the Kirkland, Argonaut and Gauthier sections, and will probably carry the surveys to the Quebec boundary. Crown Reserve developments

at Pancake Lake are understood to be very satisfactory. The Argonaut has recently found good values on the 500-foot level.

**BALDWIN.**—The recent discovery on the Baldwin property, Boston Creek area, has been drifted on for about fifty feet, and is stated to give satisfactory assays.

**RECEIVERS OF STOLEN GOLD ACQUITTED.**—A good deal of resentment is felt in Northern Ontario over the recent acquittal of R. Kleiser and Leslie Donnelly, who were arrested in connection with the theft of precipitates from the Kirkland Lake Gold Mines. Donnelly is a manufacturing jeweller, who melted down the precipitates and acknowledged having received precipitates of a gross value of \$17,500, for which he paid \$15,119. When asked for a reason for his frequent trips to Haileybury to receive the material, he stated that he was working hard and took these trips for relaxation. He stated that the vendor of the precipitates had told that he and others were interested in a mining property in Kirkland Lake, and that on account of trouble between him and his partners, the precipitates had to be treated privately. Kleiser was tried before a Jury and stated that he had sold gold to the value of \$3,800, which he stated he had received from Ed. Dean. He held out \$360, and stated this sum was on account of his efforts in financing the Reliance property in Cobalt, of which Dean was one of the lessees. Dean and Beswick, the other two men who were arrested in connection with the same series of thefts, will come up for trial at New Liskeard on January 29th.

**FATAL ACCIDENT.**—A most unusual accident at the Tough-Oakes Mine of the Kirkland Lake Proprietary, resulted, a few days ago, in the death of Hilary MacAlindan and the narrow escape of two others. MacAlindan, with his partners, was loading a round of holes in the back of a stope, and were over a chute which had been hung up. The arch suddenly gave way and MacAlindan was drawn down the chute and buried in about ten feet of rock. He did not seem to be very seriously injured and his partners were able to communicate with him. He soon stated, however, that he was burning and asked for water to be poured down to put out his carbide lamp. One of the men went to get the water, and when climbing up the ladder with a pail, fell a distance of 25 feet, breaking his arm and two ribs, and before a sufficient supply of water could be obtained, MacAlindan had apparently died. When the body was recovered it was found he had broken his arm, but death was caused by a very severe burn in his thigh, from the carbide lamp.

**PORCUPINE.**—Orders have been closed for two very large crushers for the Hollinger mine. Officials of the company have stated that the expected dividend increase will not materialize until the question of power is settled.

Dome officials state that no increase in milling capacity is anticipated for the present, and that production will be maintained at about 1100 tons per day. Underground development on the lower levels is stated to be very satisfactory. In order to maintain the present output, the Dome finds it necessary to use its steam plant.

A new company, called the Northern Mineral Lands Corporation, with a capital of \$5,000,000, has been formed by interests connected with the Premier Paymaster Mines in Porcupine and the Crystal Copper Company of Butte, Montana. The new company will take over a group of claims adjoining the Paymaster, and it is stated that the vein system of the Paymaster is believed to extend into this ground. In the same section the Clifton is preparing to continue its shaft to a depth of 600 feet. The treasury has been filled to the extent of \$75,000 by the underwriting of 250,000 shares of treasury stock at 30 cents.

The Hollinger has made a further payment of \$296,250 on account of the purchase price of the Schumacher Gold Mines. This will probably be followed by another distribution of 25 cents a share by the Schumacher. The total amount distributed to Schumacher shareholders probably not exceed 83 cents a share. The purchase price amounted to 89½ cents a share, but as there were some debts to be paid off, this, together with the cost of distribution of the money to the Schumacher shareholders, will be deducted.

The Holtrex Gold Mines is arranging to purchase a mining plant. A shaft has been sunk by hand to a depth of 40 feet, and this will be continued for several hundred feet.

It is expected that the power from Indian Chutes on the Montreal River will reach Porcupine next April, and until power from that source is available the Davidson will discontinue underground work. Diamond drilling will be carried on in the meantime. Two holes are now being drilled, which will reach a depth of approximately 2000 feet. The company recently announced that favorable results had been met with.

**LIGHTNING RIVER.**—The Mining Corporation has decided to drill its claims in the Lightning River district. Surface exploration has been carried on for the past year, and two wide mineralized zones have been encountered, which carry encouraging values. Sinking is also being carried on by the Abitibi Gold Mines on their claims, which are close to the properties that the Mining Corporation have under option.

**CONIAGAS-BEAVER AGREEMENT.**—The Beaver company has announced the terms of the agreement made with the Coniagas, under which the latter company will operate the Beaver, Badger and Prince-Davis properties at Cobalt. The Beaver plant will be put in shape by the Coniagas at its own expense and mining operations will be carried on by the latter company. After deducting the actual expenses of mining and milling, the profit derived from operations on the Beaver property will be equally divided between the two companies. The Coniagas also undertakes to carry on development work on the Prince-Davis and Badger properties by the extension of the Beaver working, and the Beaver is to receive 10 per cent. of the net profits from any ore recovered from these properties, or from any other properties worked through the Beaver shaft. The agreement extends for a period of ten years, with the privilege of renewal for another ten years.

Returns to the United States Geological Survey indicate an anthracite output during 1922 of 52,000,000 tons, against 90,000,000 tons for 1921, the 23 weeks' strike being responsible for the difference.

## BRITISH COLUMBIA

**ADDRESSES BY RESIDENT ENGINEERS.**—Instructions have been given the Resident Mining Engineers of the six Mineral Survey Districts of British Columbia to arrange to address the Vancouver Chamber of Mines should their itineraries take them to that city or thereabout in the course of the next few months. This step was taken by Hon. Wm. Sloan, Minister of Mines, in compliance with a request from the Chamber of Mines for assistance in connection with the preparation of its winter programme. Wm. M. Brewer, of Nanaimo, already has told the story of mining development in the Vancouver Island and nearby mainland zones to a Vancouver audience. He is to be followed by John D. Gallowsay, of the Northeast Survey District, who now is visiting Victoria and who will devote much of his time to impressions of present conditions and the future of the Cedar Creek placer gold discoveries. A. W. Davis, of the Central Survey District, headquarters Kamloops B. C., will appear before the Chamber in the course of a few weeks. Mr. Davis was appointed to this position last year, succeeding the late R. W. Thomson. He is a returned soldier as well as a competent and energetic mining engineer. At the front he worked up to the rank of Major and his services were recognized by decorations. In British Columbia he has been in the employ of the Consolidated Mining & Smelting Co., is well known to most mine operators, and since receiving his present appointment has taken hold with enthusiasm and encouraging optimism. It will be interesting to hear what Mr. Davis has to say of the mineral possibilities of the great central district of which he has been given supervision, in the way of mining, by the Provincial Government. P. B. Freeland, of the Boundary District; A. G. Langley, of the Kootenays; and George Clothier, of the northwest, where flourishes the great Premier Mine, no doubt will be coming to the Coast later on and Vancouver mining men probably will have the opportunity of listening to talks on their various districts before the lecture programme of the Chamber of Mines concludes.

**HYDRAULIC MINING FOR SILVER.**—With reference to the Slocan District, of the Kootenays, there are few who know that silver once was mined by the hydraulicking process in that section. The Minister of Mines' Report for 1897 is authority for this statement, a report by William A. Carlyle, then provincial mineralogist, containing the following interesting account of the operations of the Wonderful Mine. "The Wonderful, 34.50 acres, Crown Grant, and the Lookout and Columbus mineral locations, situated on the mountain slope about one mile west of the Ruth and Slocan Star and south of the branch of Carpenter Creek, are owned by the Wonderful Group Mining Co. The mining operations conducted during the past season on the Wonderful were unique. The property had been under bond to Jno. A. Finch, who had done over 2,000 feet of underground work, mostly along the supposed course of a vein, but with not very successful results, only two carloads of ore being shipped from these working in 1895. Ore was found scattered through the wash and the much shattered shales near the surface so the company decided to prospect the claim by bringing water from one of the small streams in a flume and then letting it cut its way down through the wash to bed-rock as it rushed down the mountain side to Miller Creek. Water was turned on on June 18th and it was found that pieces

of galena ore were being left in the bottom of the cut, and this prospecting then developed into hydraulic mining, the water being allowed to run for several hours, when there would be a "clean up" of tons of high-grade ore, with the result that over \$25,000 were thus won. As the work proceeded it was seen that the mineral-bearing wash or debris was not more than 100 to 120 feet wide while the real "pay dirt" had a much less width than this. It was seen in the cut that as the channel wore down it left on either side country rock apparently in place. In the pay dirt there was not only the solid ore but much decomposed mineral, all of which latter of course was swept away, only the boulders of galena, perhaps with the surface decomposed, remaining, one block of solid galena weighing over 13 cwt. While some believed that the ore had been brought down from the vein higher up on the mountain side, the fact that this ore was found only in a narrow channel, and that immediately above the slope of the mountain ran back with a gentle rise, led to the belief that the washing was being done very close to the vein, if not immediately above it, and this conclusion has apparently been confirmed, as this washing is now reported by the manager to have disclosed the solid vein in place, with a strike S. W. and N. E., and regular underground mining has begun." If these unusual conditions have since been explained the reports do not seem to give the explanation. The circumstances, however, are a good illustration of the richness of the ore of the famous Slocan and are of special interest at the moment because of the expressed opinion of A. G. Langley, resident mining engineer, and other mining men that this District's revival has only commenced and that it will be heard from to some purpose in the course of the next few years.

**AN APPEAL ON BEHALF OF PROSPECTORS.**—Addressing a joint meeting of the Vancouver Chamber of Mines and the Canadian Institute of Mining and Metallurgy, it was stated recently by George W. E. Winkler, an operator of Victoria, that there are but 700 prospectors in this Province and that this number would continue to shrink if business men did not wake up to the situation. It was necessary to find work for them in the winter. A tentative suggestion made by Mr. Winkler was that a syndicate or company of business men be formed, each member of which would put up \$50 or \$100 a year, and that from these funds from eight to ten selected prospectors be put in the field each season with an adviser who would have sufficient knowledge of mining to know when to proceed with the development of a prospect. The amalgamation of the Prospector's Association with the Vancouver Chamber of Mines was urged, it being contended that a central organization could do good work in teaching the prospector more of mineralogy, geology and how to read the maps of the Geological Survey that are issued for his benefit.

**NEW PLACER FIND REPORTED.**—There are reports of another placer gold find in the vicinity of the 150-Mile House, Cariboo District. It is said that men have turned up nuggets while digging for water. A considerable area of ground has been staked. Further particulars are being awaited with interest.

**YUKON SILVER AND GOLD.**—A Dawson press despatch states that the Keno Hill silver camp, which last year shipped \$750,000 worth of silver ore, will produce this winter about \$1,500,000, the greater part of which will come from two mines. Last year's gold yield from the Yukon Territory is put at \$1,000,000 and it is estimated that there are resources to permit the continuation of

this for the next twenty or more years. The total gold produced by the Yukon to date is \$210,000,000.

**DRUM LUMMON TO SHIP.**—The Drum Lummon Mine, Hartley Sound, northwest coast of British Columbia, will be producing 3,000 tons of ore a month within a few weeks, according to Glenville A. Collins, engineer in charge and president of the Company. The ore, carrying values in copper, gold and silver, will go to the Anyox Smelter, Granby Consolidated Mining & Smelting Co. D. J. Williams, formerly of the Rocher de Boule Mine, Hazelton, is expected to become general superintendent of the Drum Lummon. Since last May there have been 30 men employed at the mine and \$60,000 has been spent on development and equipment. A 1100-foot wharf has been constructed, three quarters of a mile of standard gauge railway has been completed, a half-mile aerial tramway has been installed and a 120 horse-power compressor plant installed.

**PROMISING PROSPECT IN USK DISTRICT.**—Douglas M. McKay, mining engineer, of the Utah Consolidated Mining Co., Park City, Utah, is quoted as stating that conditions for mining in the northern British Columbia district of which the town of Usk is the centre are favorable. This is the section through which the Grand Trunk Pacific Ry. runs. Mr. McKay visited Usk last summer, investigating the mineral holdings of the Kleanza Co. Ltd. He says that prospecting and mining here have been impeded during the past twenty five years because of lack of transportation. This now is remedied and Mr. McKay expects that capital will be available for the exploitation of the district's resources because "they deserve it." No mines have been opened up and worked at a profit yet, but Mr. McKay expresses the opinion that the Kleanza Co's holdings, consisting of fifteen claims, should have further development. The values carried in the veins are gold, silver, and copper which all are in the sulphides, the quartz gangue being barren. He continues: "The ore is quite high-grade and more work ought to be done to determine the nature of it and to trace the fissures. At present they are exposed for only a few feet. The ore, if found in quantity, will be of a milling grade and will be susceptible to concentration."

**PROTEST AGAINST CHARGE OF COPPER DUTIES.**—Fred A. Starkey, commissioner of the Eastern Boards of Trade of British Columbia, has voiced the opposition of that organization to the suggested admission of copper wire bars to Canada free of duty "under all and any circumstances", instead of only when such materials are for use in the importer's own factory. The position is taken that such a policy would have the effect of cutting the feet from under the copper industry of British Columbia. Wire requirements are said to constitute the greater part of Canada's copper consumption and to place it on the free list would be a serious blow to refining in the Canadian West. Mr. Starkey's wire follows: "Strongly protest against concession being granted to eastern manufacturers admitting copper wire free. Should such unwarranted favors be granted eastern factories, copper refining in British Columbia will be utterly destroyed. If government would grant adequate protection to manufacturing of copper rods, it would result in 500 additional employees being given steady work."

**COAL MINE CLOSED.**—No. 5 Mine, Cumberland, Canadian Collieries (D) Ltd. has been closed down. Temporarily there will be no production from these workings, although the mine plant and equipment will be kept in condition for the resumption of operations when conditions warrant it.

## NOVA SCOTIA

**WABANA OPERATIONS CURTAILED.**—A few weeks ago we reported the iron ore industry of Wabana, Newfoundland, to be in a flourishing condition, with good prospects for the current year. But the war cloud has lowered and cast its darkest shadow over the horizon with harmful effect. It is stated that the German ore contract with the British Empire Steel Corporation has been cancelled. Let us hope that this is not so, but marks only an interval pending readjustment of the conditions between France and Germany. As it is, it will effect the iron ore mines of Newfoundland and throw hundreds of men out of work during the winter months.

The preparations for the year's output of ore are usually made in the winter season when shipping is quiet; but it was the intention this year to develop the mines and stock a larger quantity of ore than usual, which would have given employment to a greater number of men. However, "the best laid plans of mice and men gang aft agley" and this is only one other plan gone that way.

**NEW ORDER FOR RAILS.**—The British Empire Steel Corporation, after finishing an order of twenty-five thousand tons of one-hundred pound rails, has begun work on some for their own use. They were not quite finished when a new order for twenty-five thousand tons of eighty-five pound rails was received from the Canadian National Railways. This will help out the labor situation, as it was beginning to be feared that several hundred steel workers might be laid idle again.

**COLLIERIES BUSY.**—Despite snow storms, the Nova Scotia collieries have got away to a good start in 1923 and the output of January up to the present is double that of last year. The average daily output is over four-

teen thousand tons, while it was only seven thousand tons in January 1922. A new record since pre-war days was made lately when the output bordered on sixteen thousand tons. Several of the collieries are double-shifted, while much development work is going on in many of the others.

**ELECTRIC MINE EQUIPMENT.**—No. 24 Colliery, the first coal mine in Cape Breton to be fully electrified, is giving good results. The electric coil-cutting machines are proving a success, and the output is rapidly increasing. The experience gained in this mine, whose rise working lie near the surface, will be of great benefit when electric motive power is introduced into the deeper collieries.

If one may judge from the rumors afloat, a Cape Breton company will begin the making of salt this year by the process of evaporation, the gold mines may see a better year, and a new industry to mine torbinite may be started up. The oil of this last mineral is said to be in greater quantity than in shale.

Official preliminary report of metal production in California during 1922 indicate a total value of \$21,625,600, an increase of \$673,000 over that of 1921. Gold production, which was diminished somewhat by the disastrous fire at the Argonaut mine, was \$14,845,000, which is \$860,000 less than in 1921. The yield of silver was 3,181,200 ounces, which is a reduction of 448,000 ounces from the 1921 production.

In common with the other Anglo-Saxon nations, Australia has established a bureau for the establishment of standards, the Commonwealth Engineering Standards Association.

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars** relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**
- Summary Report.** The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memoir 108.** The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

**The SYLVESTER  
Hand Car Motor**will save  
time and  
money for  
you

Can be attached to any standard hand car.

If you are already using pump or push cars on your surface tracks it will pay you to install this efficient outfit on them.

The extra work your men can accomplish and the time saved will soon pay for them.

We manufacture a complete line of hand cars — motor, pump and push types. Our equipment is in use on every railroad in Canada and giving excellent service.

Let us send a copy of our catalogue illustrating and describing our entire line.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, tale and zinc. This Province has the largest deposits on the continent of tale, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

**THOS. W. GIBSON,**  
Deputy Minister of Mines.  
TORONTO, CANADA.

## NOW READY FOR DISTRIBUTION

**T**HE new Link-Belt General Catalog No. 400 contains 832 pages of practical mechanical information on elevating, conveying and power transmitting machinery and accessories — chains, sprocket wheels, buckets, gears, screw conveyors; in fact, it combines the complete Link-Belt products with those of our H. W. Caldwell & Son Co. plant, now owned by our Company.

It is the most complete catalog we have

ever issued. Use it as your guide in preparing plans for your material handling and power transmission equipment.

Engineers, architects, superintendents, purchasing agents, and those responsible for production, should have a copy. We shall be pleased to send the book to the right man in your organization, if it can be used to our mutual advantage. Address our nearest office, on your letterhead, giving your name and position.

CANADIAN LINK-BELT COMPANY, LIMITED

TORONTO—Wellington and Peter Streets

MONTREAL—10 Gauvin Lane

# LINK-BELT

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, \$76,177,403; Lode Gold, \$105,557,977; Silver, \$55,259,485; Lead, \$48,330,575; Copper, \$166,393,488; Zinc, \$21,848,531; Coal and Coke, \$225,409,505; Building Stone, Brick Cement, etc., \$34,072,016; Miscellaneous Minerals, \$1,210,639; Making its mineral production to the end of 1920 show an

**Aggregate Value of \$734,259,619**

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for the year 1916, \$42,290,462; for the year 1917, \$37,010,392; for the year 1918, \$41,782,474; for the year 1919, \$33,290,313; 1920, \$35,543,084; 1921, \$28,066,641.

**Production During last ten years, \$336,562,897**

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

## We Meet Your Specifications

We are prepared to furnish you with the exact flotation reagent you need. If you desire, our technical staff will gladly co-operate with you in the grades of flotation oil which will best meet your requirements.

As soon as the specifications have been established, we will guarantee strict adherence to them and absolute uniformity in every shipment. We can do this because Hercules Pine Oils are produced under rigid chemical control of every process.

We will supply you with data on any of our flotation reagents and will also furnish methods which can be used in your own laboratory to test flotation oils and to detect adulteration.

## Mining Plant FOR SALE

We are offering for immediate delivery the entire plant of Moose Mountain, Ltd., located at Sellwood, Ont. Partial list consists of:

- BOILERS** —  
1 400-h.p. B. & W. unused boiler; 1 60-h.p. locomotive type boiler; 1 25-h.p. locomotive type boiler; a number of small vertical boilers.
- CARS** —  
3 all-steel, full M.C.B. flat cars, 40 ft. long; 5 wooden flat cars; a large number of kiln, mine and quarry cars.
- COMPRESSORS** —  
1 25 x 15 x 24 Canadian Rand; 1 as above, but direct driven by 550-K.V.A. motor, 60-cycle, 3-phase, synchronous.
- CRUSHERS** —  
1 36 x 48 Buchanan; 1 24 x 36 Farrel; 1 48-in. Symons Disc; 1 No. 4 McCully; 2 No. 2 McCully.
- GENERATOR SETS** —  
1 750-K.W. Westinghouse Turbo Generator, 3-phase, 60-cycle, 550-volt, 3,600 R.P.M. complete. This equipment is unused.
- BRICKPLANT** —  
Consisting of 3 American Clay Machinery Co. presses; 2 Grondall tunnel kilns; 1 gas producer; a large number of cars.
- LOCOMOTIVES** —  
2 American saddle tank locomotives, standard gauge, 10 x 16 cylinder.
- MILLS** —  
4 6-ft. x 48-in. Hardinge mills; 1 8-ft. Hardinge mill; 1 No. 86 Marcy mill.
- MOTORS** —  
A large number of 3-phase, 60-cycle, 550-volt motors, up to 250 h.p. All motors above 50 h.p. are wound rotor.
- MACHINE TOOLS** —  
Consisting of lathes, planers, pipe and bolt threaders.
- PUMPS** —  
A large number of centrifugal, turbine and vacuum pumps.
- TRANSFORMERS** —  
9 275 K.V.A. transformers, primary 30,000, secondary 2,300 and 550.
- SUNDRY** —  
There are also available a large number of classifiers, conveyors, drills, filters and electrical supplies and equipment.

## TORONTO MINING TANKS

As all our Mining Tank stocks are well seasoned and air dried to give them longer life, Toronto Mining Tanks give efficient service under severe conditions. Carefully machined — built with the utmost precision. The TORONTO Mining Tank illustrated above is built from B. C. Fir, Redwood, Gulf Red Cypress or White pine. Surfaced two sides — jointed and doweled to give maximum strength. Securely hooped by round wrought iron or steel hoops, joined together by extra heavy lugs.

Illustrated folder, information and prices gladly furnished.

### WILL THE TRADES UNIONS SURVIVE?

Trades unionism is now on trial throughout the world. The modern movement for the organization of labour has grown with extraordinary rapidity since its inception, and now organized labour constitutes one of the greatest single social forces in western Europe and in North America. Its power is great and its potentialities even greater; it will stand or fall on the rational use or the abuse of that power.

Of recent years the power conferred upon organized labour by virtue of its unions has been characterised more by its abuse than by legitimate use. The ideals expressed by the best among its leaders and incorporated in the formal declarations of policy of the unions appear, however, to actuate very, very few of the leaders or of the private members. Selfishness, exclusiveness and an utter disregard for the rights of the rest of the world (who are, incidentally, in the majority) have appeared in so many shapes and guises as a result of trades union activities that the good work the unions have accomplished appears insignificant in comparison.

In Italy the state of affairs became insufferable last November. The trades unionists by their crazy demands and scarcely less rational conduct almost brought Italian industry to a standstill. The mercurial Italian temperament provided a solution for this impasse; a national hero, Mussolini, rose to the occasion and at the head of his bands of Fascisti rapidly put the trades unionists in their place, restored a stable government and set the wheels of industry revolving once more.

Events march with more deliberation in Anglo-Saxon communities. In spite of an overwhelmingly industrial population, Britain has never yet been dominated by labour's demagogues; the British working man is, at bottom, a shrewd fellow and round. The more moderate and thoughtful, as well as more honest, of labour leaders held important office and did yeoman service in the coalition government during the stress of war-time and the struggles afterwards to regain normal conditions. Still, the industrial depression of 1921-22 brought the occasion for a most decided "show-down" between organized labour in

Britain and the rest of the population, and the unions submitted to the inevitable with more grace than might have been expected of them. The British workmen is learning once more that he must work, and work hard, for a living, and there is no longer any need for the "middle class union" that was mooted.

Australia is at present in the depths of an industrial depression brought about almost exclusively by the refusal of her organized workers to do an honest day's work. With natural resources and favourable conditions that are enjoyed by few other parts of the world, the Australian is not now making a particularly good living, simply because he refuses to work for it. He is looking for something for nothing — and is getting nothing for nothing, thereby illustrating a truth that is axiomatic to all, but the misguided labour leader and his dupes.

On this continent the issue has not yet been so clear-cut as it was recently in Britain and more recently in Italy. We are still too prosperous to worry about a little thing like the basis of our industrial production. Anyhow, most of us still retain the habit of working, inherited from our pioneer ancestors, not far back. But sooner or later we must face the issue, and the issue will be between the forces of selfishness and the forces of decent, Christian-like co-operation; between the man whose vision is confined to himself, his union, or his class and the man whose vision includes the rest of his countrymen as well.

If our labour unions are to survive this test (and we sincerely hope they may do so) it will be by virtue of a broadening out of their policies so as to be less exclusive of the other parts of the modern civilized community. The locomotive driver must realize that the factory hand working for low wages virtually hands over to him each week part of what he has earned, in order to swell the fat railway envelope to its present inordinate dimensions; the locomotive driver is to just that extent a parasite and a burden on the community. The coal miner who works five hours a day and five days a week will have to depend for part of his livelihood upon the scrub-woman who buys his coal at an exorbitant price.

There are signs that the substantial labour leaders of Canada and the United States are reading the signs of the times and are making ready to return to the

true ideals of labour unionism. Only by such a move can these leaders preserve themselves and their unions from the nemesis that overtakes the confirmed self-seeker.

### THE MINING STOCK EXCHANGES AND THE MINING INDUSTRY

During recent months we have wondered, both publicly and privately, why Canadian mining shares have not been listed on the London mining stock exchanges. The principal reason, so far as we can determine up to the present, is that for investment purposes the operations of Canadian mining stock exchanges are a farce.

It is an axiom in mining investment that the rate of return must be such as to return the sum invested, with interest, within the life of the mine. This rate is conservatively estimated at 12 per cent. per annum, if applied to mines that are thoroughly proven and that give promise of a reasonably long life and steady production. If one included in the estimate near-mines and those of erratic disposition, the rate of return would have to be correspondingly higher.

Now, what do we find on Canadian exchanges? Consider Hollinger. It is selling today at about \$12.50 per \$5.00 share. The present dividend is 13 per cent. per annum. This gives a return of slightly over 5 per cent. to the investor who buys at this price—some-what less than half the rate it should return to be a good mining investment. True, the Hollinger is the nearest thing to an ordinary industrial concern—a gold factory—that one could hope to have; but that does not preserve it from the vicissitudes common to all mines, and does not warrant the prudent investor in allowing his hopes to outweigh his knowledge. Hollinger may demonstrate later that it is worth \$12.50 a share—we hope it will, and in fact are confident it will—but that hope and that confidence are a basis for speculation, not for investment. Hollinger is the nearest thing to an investment we have in the whole long list; we refrain from discussing any of the others.

Yes, speculation, not investment, is at the bottom of the operation of our Canadian mining exchanges. Whether the speculation is strictly honest or not, there can be two opinions; but that there is speculation, and speculation only, involved, there can be no doubt. The man who wants to “take a flyer” can get some pleasurable excitement out of the mining exchanges. The man who wants to invest his money keeps away from them, unless he grows wool on his back or is of the finny tribe.

London has available already plenty of devices for stock speculation, without borrowing any from Canada. It would add neither to the attractiveness of speculation in London nor to the reputation of mines in Canada were Canadian mining stock quotations, as extant in Canada today, listed on London exchanges. Transactions on the basis of these quotations have only

the remotest connection with actual mining operations and cannot aid the industry materially, whether they are in London, Montreal, Toronto or Victoria. What we need is capital for our growing mining industry, and we cannot see how mining stocks, grossly over-capitalized at the market price, can be an attraction to new capital.

Canadians, or at least some Canadians, are rapidly becoming aware of the fact that mining can be made a sound, paying business, much like any other line of business. There is as yet no hint of this realization on the Canadian mining stock exchanges, which at present do not appear to be a legitimate part of our mining industry. If they should become a legitimate part of the mining industry by conforming to its ideals of sound business methods, there is no doubt that they could aid the industry materially. Meantime, we can hardly recommend to our trans-Atlantic cousins that they join us in what is, in general, a doubtful speculation. We hope that, as time passes, our mining stock exchange transactions may develop at least an approach to the methods of sound investment. Only thus can they become genuinely identified with Canada's mining industry, as are the regular stock exchanges with the other phases of our industry.

### CANADIAN ARSENIC

The recent revival of the market for arsenic compounds gives point and pith to a bit of research work that has been conducted, quietly and consistently, by a little band of Canadian researchers during the past three or four years.

As is well known, the silver ore of Cobalt contains a notable proportion of arsenic, and at present constitutes the main source of arsenic in the Dominion. This is recovered as a by-product in the various plants that treat ore from Cobalt, and its annual production reached \$608,000 in 1917, principally as white arsenic. The bulk of this white arsenic was exported. By the way, there is still a standing offer, we believe, by the Ontario government of a bounty for the production of “white arsenic, otherwise known as arsenious oxide, produced from mispickled ores, and not from ores carrying smaltite, niccolite or cobaltite.”

White arsenic is virtually a raw material, the principal finished products being compounds and mixtures such as Paris green, acetate of lime, and so on. The production of these materials for consumption in Canada and their export in place of the raw material should be a decided advantage to Canadian industry.

The reduction works at Deloro produces the larger part of Canada's arsenic at present. The process in use there for separating and refining the various ingredients of Cobalt ore was devised by a professor of

metallurgy working in his laboratories in the School of Mining, Queen's University. By special co-operative arrangement with the university authorities, the research work of the Deloro Smelting and Refining Company has been conducted continuously since then in the laboratories of the university. This constitutes one of the rare instances in Canada where industrial research, under private auspices, has been conducted successfully over a term of years in co-operation with a university. The advantage is mutual, and the practice is capable of wider application.

The object of the Deloro Smelting and Refining Company is, of course, to make the most of their opportunities. One opportunity they have foreseen shrewdly lies in the manufacture of the various arsenic products from their crude arsenic. In spite of the depression in the arsenic trade since 1917, their researchers in Kingston and their operators at Deloro have laboured continuously at this task. They established accurately the scientific basis for the preparation of the various arsenic compounds (heretofore only imperfectly understood) and then proceeded to devise ways and means of applying these principles industrially. The results of these years of faithful, painstaking research should, and will, be to put the company in a position to reap the maximum of benefit from the present market for arsenic compounds.

If there are still remaining any Canadians who doubt the efficiency of scientific research, let them examine the record of the Deloro Smelting and Refining Company, which was founded on research, has been built up by research, and is still researching with an intensity that augurs well for its future.

#### EDITORIAL NOTES

Two weeks ago the *Journal* discussed in a general way the possibility of the occurrence of placer gold in Labrador, and referred to the present attempt to raise money publicly to work alleged placers there. Since then we have had private information that confirms our impression that the placer find is a barefaced hoax. This cannot be proved definitely, however, until an examination by some competent person is made of the reputed pay gravel. As this cannot be done until next spring after the snow and ice are gone, we must reserve final judgment until then. In the meantime, let the public beware!

During recent years a very large amount of research work has been done by the United States Bureau of Mines on practical problems. Lately much of this work has been done in co-operation with private institutions such as the Universities. One such piece of research work, on drill steel, has been conducted by Professor Charles Y. Clayton of the Missouri School

of Mines. It is described by him in a paper, "Hardness and Heat Treatment of Mining Drill Steel Shanks," to be presented at the New York meeting of the American Institute of Mining and Metallurgical Engineers this month. The data show a rather ridiculous diversity in present practices, and the results indicate practical rules for getting the best out of the various grades of drill steel. The investigation is still in progress, but this interim report is worth close attention.

We are pleased to have for publication today the full text of the resolution whereby the United Mine Workers headquarters executive repudiate any alliance with, or even sympathy with the Moscow "Reds." As the move was taken because of the well-known radical tendencies of the present accredited executive of the mine workers of Nova Scotia, the pronouncement is of special interest to Canadians. This may bring the following of the Sydney radicals to their senses.

The fact that a substantial number of industrial and financial leaders in the United States realize the true position of mining in the national economy is demonstrated by the widespread support given the recent Anaconda bond issue. The new corporation's assets are principally copper mines and plants for treating copper ore.

#### HISTORY — III

##### ASCENDANTS

When Earth was mostly vapour  
It was a dizzy spot;  
Small comets cut a caper,  
And everything was hot,  
As time induced a cooling  
Quite solid grew our sphere,  
The comets ceased their fooling,  
And cell-life started here.  
By aeon-long gradations  
The Scheme of Things resolved,  
And, by our calculations,  
Crude fishes were evolved.  
Through ages all unmeasured—  
Deny the truth who can—  
(O! Origin untreasured!)  
Fish-life progressed to man.  
Thus, though against our wishes,  
Resent it how we will,  
We all descend from fishes—  
And some are fishes still.  
This being demonstrated,  
Despite protesting damns,  
It scarcely need be stated—  
Geologists were clams!

# The Discovery of Porcupine

by TOM SAVILLE

Joe Moore, a Hudson's Bay Scotsman (half Indian but a whole man) was tanning a moose hide at his camp way down on the Matagama River. The bear hunt was just about over and he and his family were making ready to go into the H. B. C. Post at Fort Matagama with their winter's catch of furs. His women folk were busy outside, smoking moose meat for their trip in, and the children were playing down at the sandy beach where the canoes were pulled up. Joe noticed that there was something wrong with them for they were running up to the camp, scared like, and then soon he could hear them—"Shakanash! Shaka-nash!" (Ojibway for white-man), and sure enough there was a canoe coming round the Red Pine point.

Joe goes down to meet them and bids them welcome. "Come on ashore and stretch your legs,"—which they do.

"Are you Joe Moore?" asks the bowsman as he steps out of the canoe.

"Yes, sir, that's my name," answers Joe.

"Well my name is Parks, and I'm glad to run across you. The Factor up at Lake Matagama told me you could give me a lot of information about the routes through this part of the country. I'm employed by the Department of Mines, making a preliminary geological survey and I particularly wish to cross overland from the Matagama to Night Hawk Lake."

"Well, sir, there's a kind of a route across, but not very well travelled. I was through there last fall with my canoe as far as Kag-a-sa-ki-kun (Porcupine Lake) and put in an odd blaze. I have a bear trap set on the portage between them first two little lakes and I'll come with you now and pick it up. Then I'll make sure you don't miss that little creek where you turn off the river to go across. We'll have a little drink of tea first and then away we'll go."

So away they go, and Joe picks up his traps, and while the canoe man is cutting out a fallen tree Joe and the Doctor have a farewell smoke.

Joe is saying, "No, sir, I don't know much about rocks. About all I know is that they are hard on our birch-bark canoes in the rapids and hard on our moccasins on the portage. What kind of rock would you call this?" says Joe, poking with the back of his axe some loose rusty looking material.

"That's schist, Joe, and the way it is mineralized is indicative of carrying values in gold. Maybe you have a gold mine on your hunting ground, Joe!"

"I hope I haven't," answers Joe. "That would mean I'd have to look for another hunting ground. Well, I guess I'll be getting back to my camp now. You can't miss the route now. So good-bye, and good luck."

"Good-bye, Joe, and thanks," says the Doctor, and away goes Joe Moore to his hunting camp and the geologist to his rocks.

\* \* \*

A few years later, the scene is the same, but the atmosphere is different. Silver has been discovered and Cobalt is right in its glory. Prospectors are stampeding and spreading out in all directions. "Diabase" and "bloom" are discussed around every campfire. The

Montreal River is the happy hunting ground, and Gow Ganda is the Big Noise. About this time we found ourselves away up at Was-ac-sing (Shining Tree), a hundred miles from the jumping-off place at Latchford on the T. and N. O. Ry., anchored to a bunch of silver claims that looked right—but which we were beginning to see were put in wrong by poor transportation facilities. It was about Christmas time, my pardner and I had made a good fall hunt and were considering taking our furs into the post over at Fort Matagama.

"All right, Lisa, we'll go. I guess you'd like to see your father." (The chief of the Matagama's).

I had made a toboggan and bent some snowshoes, which she had laced with babish, and with our team of husky dogs we would travel right. We got our outfits made up that night ready to start at daybreak, and we figured we would only camp out one night. Away we went bright and early, the huskies glad to be on the trail after being tied up on purpose for some days previous so as to make them keen to travel.

We had no sooner got away from the camp than the sun came up, flushed and angry looking, and we knew we were in for some kind of dirty weather. It wasn't long getting down to business. It sure did snow. We did well to get as far as Wa-sa-pi-ka (White Rock) and there we camped for the night,—a fire the first thing,—and while I was using one of my snowshoes for a shovel, pulling the snow off a little side-hill and banking it around, half moon fashion facing into the woods, my pardner had unhitched the huskies, tied them out of the wind, unlaced the toboggan and had cut some poles and balsam brush. The poles I stood up round the fire, the brush in front of the fire and with the toboggan cover thrown over the poles and with a good fire high up in front of us and the heat throwing down and into our "nest", fat moose ribs a-sizzling, speared on sticks, the tea pail just about boiling, lots of wood cut to last all night, the huskies wrangling after being fed, and with clean change of wollen socks and moccasins and a good wash up in the snow, and with that tired but pleasurable feeling, we could truthfully say, "This is the life!"

In the morning I measured the snowfall with my axe-handle—14 inches on the level; but we weren't going to turn back after getting this far, but we knew that a heavy fall of snow such as this would soon raise the slush over the ice, and that would make slow travelling. Anyway we broke camp, laced everything up tight on the toboggan, hitched up the huskies and went to it, my pardner driving the dog team and me breaking trail—some exercise, I can assure you!

We came in sight of the Post two days after New Years. As soon as we got close my pardner suggests giving the dogs their wind, so we pull in behind a point and make a fire and my suspicions are confirmed. The wife dolls up—fancy, beaded buckskin moccasins, silk worked gauntlets, sash and all, and with some beaded buckskin work she trims the huskies up too, and we pull into the Post in style.

Everybody is out to welcome us. My pardner is soon away with the Factor's daughters, my huskies unhitched and fed and the Factor has conjured me into his den for a snort of Hudson's Bay Special. While I'm thinking

what a fine old world this is, after all, in comes the Stranger.

"Shake hands with another prospector, Tom," says the Factor.

We shake, and he tells me his name is Daigle—R. B. Daigle from the West; that he has met Joe Moore, who has showed him some rock samples and that he is planning on spending the following summer prospecting on Joe's hunting ground.

Well, we sure do enjoy ourselves at the Post for a few days. Everybody is happy and we are just like one big family. We dance the Bear, the Duck, the Fisher, the Rabbit,—everything but the war dance. We played out two fiddlers and wore out the drum. By this time the slush had frozen and the lakes were in good shape to travel. So after shaking hands all around, and a few dog fights, we hitch up what's left of ours and hit the trail for Shining Tree.

\* \* \*

Later in the same year after the freeze up, I am down in the Big Smoke and who should I run into but the "Stranger" I had met up at Fort Matagama.

"Hello, Tom, I'm looking for you. I heard you were in the city. Come on down and have lunch with me and I'll tell you about that Porcupine expedition."

He tells me that he went down there with a white man, Bob Mustard, and a Hudson's Bay Scotsman, Bill Moore. They packed in a big outfit, enough for the season, including blacksmith outfit. They camped on the first little lake from the river and stayed right there, stripped and trenched and sunk a pit about eight feet deep and took a lot of grab samples, and just got out to Biscotasing on the C. P. R. before the ice got them. Daigle had his assays made and the assay was four dollars and twenty cents.

"I don't think I'll record them, Tom,"—and he didn't.

"I'm going to make a trip up into Ungava," he told me, "and expect to be gone a couple of years, and I want you to put me in touch with a couple of good Hudson's Bay Scotsman." Which I did, and away they went to Ungava.

The mining world knows what happened while they were away,—Bannerman with his first discovery,—Hunter sees it on Porcupine Lake, but Jack Wilson makes the "Big Discovery" on the Dome. This starts the Stampede and brings in Benny Hollinger and the bunch, who stake, and Benny Draws the Big Prize—the Hollinger Mine.

## AN ENGLISH VIEW OF CANADA'S GOLD FIELDS

*The following, which has appeared editorially in The Mining Journal, London, illustrates well the present English view of gold mining in Canada.*

At the opening of the New Year the question which most of our readers are asking themselves—When is mining going to revive?—naturally presents itself with special emphasis. In the past public interest in metaliferous mining has to a predominant extent centred on the production of gold. Now gold, while it has at times such as those which we have recently passed through some commodity value, is dependent for its quantity of production mainly upon discoveries of new fields or extensions of old ones. We are once more

approaching the time when gold may be expected to have a fixed value—fixed, that is, in relation to currencies, for in relation to commodities the purchasing power even of gold must be an ever-fluctuating one. The importance of a fixed value is that there is no fear of over-production, and consequently no interference with the free market.

The production of gold was on the decline before the war, because of the failure of the prospector and miner to reveal fresh fields to replace those being worked out. The decline was extraordinarily intensified during the war, and those who regard an extensive gold supply as at all indispensable for the smooth course of international business in future years are conscious of considerable uneasiness at the steadily narrowing volume of supply. In the Western States of America interest in gold mining among capitalists continues to decline; Australia has fallen very heavily, and will continue to do so; the Rand decline has perhaps been stayed, but the future is too dependent on conditionals to permit of a positive asseveration here; India looks like some recovery, but the potentialities of increase are not such as to influence the general situation of supply. Mexico may show us substantial developments in years to come, but gold mining is of secondary importance among the mineral products of the country, and if more settled conditions permit of a rapid development of Mexico's mineral riches we shall probably see other minerals reflect this movement to a greater extent than gold. Russia will probably show some betterment, but in common with other industries of the country the near future is much too uncertain to permit of any estimate being made.

There remains, therefore, only one producer which certainly promises us substantial development in the production of gold — viz., Canada. The impression perhaps prevails that Canada last year showed less progress than was hoped to be the case during the spring and early summer when some promoting activity was apparent in London. We do not think, however, that this impression is justified. The Ontario statistics for the first nine months of 1922 show an output for the Province of 750,000 fine ozs., and allowing for the steady expansion that is going on the year's total may well reach 1,100,000 fine ozs. As the Government report points out, the increased crushing capacity of the Hollinger mine is shortly to be available, enlarging the capacity to 7,000 tons per day, an increase in the milling capacity equal to the present output. How far this increased rate of crushing may be attended by the treatment of lower-grade ore we do not know, but allowing for the advent of fresh producers during the year it seems not beyond the bounds of possibility that Ontario in 1923 may produce as much gold as Western Australia did in its best days. In any case, whether this result be realised in the current year or no, there seems every reason to expect that the Province of Ontario will, ere long, be producing at a greater rate than Western Australia ever did.

Under these circumstances it is certainly remarkable that gold mining prospects in Canada have not attracted general attention in this country. Conditions, of course, are not what they were before the war, and New York is much nearer than London; but when due allowance is made for these conditions, we cannot help the conclusion that there is far less enterprise existing at the present time among those connected with mining than was the case at the beginning of the century. The chief reason is no doubt the disappearance of the nu-

merous smaller interests and the domination of the position by a few big groups more or less inter-allied. Probably the policy of such big concerns is to refuse prospects out of which small syndicates in the past might have done well, and take up only those which are capable of early flotation at high capitalisations, so as to secure a large and rapid profit on the turnover. In the end a policy of this kind, while profitable perhaps to the individual group, must be very restrictive of local enterprise in gold mining.

We gather that at length somewhat more attention is being paid to Canada by the big gold mine promoting interests here, but considering that Ontario is British territory not more than a week distant from London, the evidences of a realisation of the potentialities of the situation are most disappointing. Not only is the production itself impressive, but the physical features are noteworthy. The area of the newer gold discoveries in Canada is very extensive, and though Northern Ontario is by far the most important, other Provinces also have their discoveries of promise. Then, again, and even more important, gold is met with under quite new geological conditions. In earlier days Porcupine, like Kalgoolie and the Rand, was depreciated because the geological conditions were not familiar. The lenticular character of the deposits was pointed to as evidence of patchiness. Now, however, practical experience is leading to the belief that the lenses have a definite relation to one another: those who have worked most extensively on the field believe that an indicator system can be detected. It is also claimed that at Porcupine, at any rate, the values have improved with depth, and that the payable width of the lenses is often extraordinary. As the gold occurs, not in defined veins, but disseminated into the country, it is impossible to determine stopping widths except by actual sampling, and this, together with the necessity of seeking fresh ore bodies laterally, has made diamond drill boring a remarkable feature of the plan of development.

The Provincial Government has afforded every assistance for the installation of electrical power plant, and, consequently, diamond drilling can be carried out with a speed and cheapness unprecedented in the history of earlier gold fields. This is a factor which enables mines to show a development rate to which we are unaccustomed.

Ontario depends for her yield at this year to the extent of nearly 90 per cent. on the three Porcupine mines—Dome, Hollinger, and McIntyre—but the most encouraging feature of the situation is the large number of new areas of promise. In an article elsewhere in this issue Mr. Gwyn-Williams, who spent last summer and fall in investigating many of the new camps, discusses the showing and leading geological features of a number of the districts. His paper is probably the most comprehensive record of individual observations which has yet been published, and should go far to convince capitalists that there is a very extensive field inviting attention.

English engineers encounter in Canada many conditions to which they are unaccustomed, and which they are apt to think are better managed under the mining laws of other States. But no mining law will give satisfaction to all comers, and if the country continues to make the rapid development which those who have observed it most closely expect, conditions of tenure and promotion will soon be overlooked. The mining community in Canada is a vigorous one, with imagination and constructive ability, and the Provincial Governments generally are hardly likely to make the mistake, which

has so fatally reacted upon Australia, of subordinating the interests of capital to the political exigencies inseparable from a dependence upon a Socialistic Labour Party.

## LETTERS FROM READERS

### *A Sermon to the Editor*

To the Editor,

Can. Mining Journal

Sir:-

In your issue of November 17th, under the heading "Letters from Porcupine — Inside Stuff" there appeared the following:-

"While examining a lot of rich specimen ore displayed on the dump of a Porcupine mine, a super-ethical Canadian Professor was observed surreptitiously jamming a few of the choicest pieces into his side pocket. Technically that professor is quite as liable to arrest as were recently extradited children of sunny Italy."

To those who were in Porcupine last autumn (and to others also perhaps) this obviously refers to myself. The only dump on which rich specimen ore was displayed was the Paymaster, the only professor there at the time was myself. A photograph of the dump with myself in the group was widely published.

In your issue of Jan. 12th., in an Editorial Note you state that "the implication in this case is quite without foundation." This releases you as far as I am concerned but you still leave an implication against "all professors" and treat the whole matter in anything but a serious manner.

You are a Queen's man, a son of a professor, a son of a Dean of Professors, but I believe I know Queen's professors better than you do. I know intimately any who are likely to visit Porcupine, and I cannot conceive of one of them surreptitiously pocketing high grade or choice specimens of any kind. We have most ardent professors of mineralogy and of geology in Toronto and I have accused them of sundry and various lapses, but they would not do that. Why should they? They are treated at all the mines with the most open-handed hospitality. The managers and the members of their organizations give freely of their time and of their information and equally freely of all specimens that could be of use to the students. To turn round and pocket surreptitiously would be a gross return. This is not super-ethics, it is very ordinary, common decency. To do otherwise would be very dirty.

You and your *Journal* are trying for a high and honourable place in mining affairs in Canada. You have made a good start and we have told you before that we appreciate it. But in this case you allowed your correspondent of "Inside Stuff" to make a statement that was absolutely untrue. He accused a professor and engineer not only of a most unprofessional thing but of a dirty thing. A letter or telegram of inquiry would readily have given you the truth. Your own evidence in the matter shows that its object was to irritate.

Now this is not typical of yourself, Mr. Editor. I cannot conceive of you surreptitiously pocketing high grade. Also I am glad to say that such "inside stuff" is not typical of the *Canadian Mining Journal*.

Don't let it occur again.

H. E. T. Haultain

Duluth, Minn.

# Investigation of a British Market for Canadian Non-Metallic Minerals\*

By HUGH S. SPENCE, M. E.

The following notes on factors governing the market in Great Britain for certain non-metallic minerals produced in Canada comprise information gathered in September 1922 in the course of a survey of the British trade, as represented by some of the more important consumers, brokers and importers of such materials. It should be understood that the general condition of trade as mentioned in the introductory paragraph is that obtaining during the last quarter of 1922; this condition, it is to be hoped, will gradually change for the better.

## Introductory

The moment at which the above survey was made proved to be an unfortunate one for attempting to arouse interest with the British trade in Canadian minerals, owing to the general industrial depression and the political uncertainty. Trade in general in Great Britain is in a very depressed condition, and recovery from the post-war slump in many industries has been slow and hampered by the coal and engineering strikes. The present unstable exchange, also, is having a very prejudicial effect upon industrial activity. In addition to the fluctuating exchange curtailing buying of raw materials by rendering manufacturers disinclined to lay in stocks, the more favourable exchange with many European countries having resources of the minerals required naturally makes it to the British importer's advantage to buy from such countries, rather than from Canada. The depreciation of the franc, for instance, makes it to the British importer's interest to obtain his graphite from Madagascar, a French possession, and the same holds good of mica, of which mineral Madagascar has recently been shown to possess important deposits. The relatively low production costs in countries supplied with black labour, such as the various French and British colonial possessions, still further works to the disadvantage of Canada in competing for the British market.

The result of the enquiries instituted goes to show that Great Britain at the present time is not buying at all heavily of non-metallic minerals; that manufacturers in some cases are carrying considerable stocks both of minerals and of manufactured goods; and that mineral brokers, in consequence, are not greatly interested in Canada as an immediate source of non-metallic minerals. The Atlantic freight, also, (at present about \$6 per ton from Eastern ports), plus the rail charges from point of production to the Atlantic seaboard, constitute a serious obstacle to trade relations. In the case of feldspar, for example, these combined freight costs practically equal the c.i.f. selling price of feldspar in Great Britain today.

In order to assist Canadian producers who may be desirous of seeking an outlet for their mine products in Great Britain when general trade conditions shall improve, the Mines Branch has compiled lists of the more important British consumers, dealers and brokers in many of the more important minerals — particularly the non-metallics. Copies of these lists may be secured on application to the Director, Mines Branch, Department of Mines, Ottawa.

**Barytes.**—British barytes producers are already feeling the effect of German competition, the German barytes being a better crude and also more carefully ground and prepared for the trade than the English. It is regarded as certain that, when conditions permit of a greater certainty of delivery from Germany, German barytes will supplant domestic or any other barytes in the English market. In September 1922, German barytes, prime white, water floated, 99 per cent.  $\text{BaSO}_4$ , was quoted at \$18 per ton c.i.f. United Kingdom.

The principal use of barytes in England is in the paint trade.

**Bentonite.**—Bentonite is a colloidal clay found in certain parts of Western Canada, and in Wyoming and Dakota in the United States. Its extremely fine state of sub-division, and its peculiar property of swelling to several times its mass and forming a mineral jelly upon the addition of water, indicate that it may prove to be considerable importance in industry. Suggested uses for the material are in the loading of paper, textiles and other fabrics, in rubber, paints, sizing of yarns, and the dye industry. Successful commercial use has already been made of bentonite in the United States for de-inking old newsprint and to increase the retention of china clay in the manufacture of paper. It has also been employed in a small way in coloured crayons, and as a component of adhesive pastes.

In 1921, the Mines Branch negotiated the shipment to the Imperial authorities in London of five tons of Alberta bentonite, to be distributed to various industries for experimental purposes. A survey was made of these industries in order to ascertain what progress, if any, had been made in the research work on the material. It was found that practically all attempts to develop a use for the bentonite had failed, and little interest was expressed in its possibilities. This is due, in part, to the expense of freeing the crude clay of the percentage of relatively coarse grit usually present. If ordinary settling in water is practised, the gelatinous nature of the water-saturated clay renders drying of the cleaned product difficult and costly. This obstacle will doubtless be overcome eventually — possibly by employing some medium other than water for washing the clay. The progress already made with bentonite in the United States gives ground for believing that further research will result in the successful utilization of the material in various lines of industry.

**Corundum.**—Brokers report that considerable quantities of corundum are now coming on the market from Madagascar and Rhodesia; these importations supplement the main supply, which is derived from India. The Madagascar corundum is in the form of loose crystals of various sizes, and is probably won from soft, weathered rock, thus dispensing with expensive mining and crushing. The Rhodesian corundum is stated to be surface float, and is rather different in character to the Madagascar. Rhodesian corundum is quoted at \$45 to \$54 per long ton c.i.f. United Kingdom, and Madagascar crystals at \$45 per long ton.

**Diatomaceous Earth.**—Dealings in this material are largely confined to one firm, the Kieselguhr Supply Company, 1 Great Winchester Street, London E. C. 2, who draw their supplies from many sources.

\* Memorandum Series, No. 6. — Mines Branch, Ottawa

A large percentage of the diatomaceous earth used in Great Britain goes into insulating bricks and pipe-covers. A quantity is also employed for filtering purposes in the sugar industry, in the refining of oils, fats and glycerine and as a filler in rubber. The annual consumption of diatomaceous earth (or kieselguhr, as it is commonly termed in the trade) for all purposes in the United Kingdom, is given as 6,000 long tons, and that of the world as 36,000 tons.

For insulating purposes, an earth of low specific gravity is demanded, colour being immaterial within limits. German kieselguhr which is considered the best on the market, averages 13-14 pounds per cubic foot. The rubber trade stipulates for a white, iron-free earth.

The price of diatomaceous earth is dependent largely on the structure and shape of the diatoms, since these characters control the specific gravity and the consequent absorptive and insulating power. Diatoms vary widely in the above respects, hundreds of forms being known; and a knowledge of diatom structure is therefore requisite to enable the value of an earth to be gauged with the help of the microscope.

German kieselguhr undergoes a washing process to remove grit, and is water-floated to ensure a uniform product. Air-dried earth is considered superior to ki-dried. Far closer attention would appear to be paid in Europe to the cleaning and grading of diatomaceous earth than has been the case among Canadian producers.

**Feldspar.**—A special effort was made to ascertain the factors governing the feldspar situation, since Canadian producers of crude feldspar have been endeavouring for some years past to enter the British market. This market has been supplied for years past virtually entirely from Scandinavian sources. Little authoritative information has been available regarding the possibilities of the British market for feldspar and Canadian producers have, therefore, been working rather in the dark when making an effort to establish trade connections with Great Britain.

A temporary shortage of feldspar was experienced in Great Britain toward the close of 1920, and during the early months of 1921 high prices ruled for both crude and ground spar. This situation being brought to the attention of Canadian producers, serious efforts were made to negotiate sales of Canadian feldspar to the British trade. These efforts, however, proved practically fruitless, since the shortage was of brief duration, and prices soon fell to a much lower level.

It was with a view to securing authoritative information on the present market possibilities that a visit was made to the Potteries district, in order to interview the chief pottery firms and potters' supplies houses. Dealings in feldspar in Great Britain are mostly conducted through potter's supplies firms, though limited sales are also effected through general mineral brokers, a number of whom were also interviewed and their views secured. The result of this investigation may be summarized briefly as follows:

The market for feldspar in England is not large, the annual consumption by all trades, including the metal-ware-enamelling industry, probably not exceeding five thousand tons. This is considered to be an outside figure, and the actual consumption in the last two years is thought to be considerably under this amount. Cornwall stone practically takes the place of feldspar in the

English pottery trade, and for various reasons is preferred by English potters. Being of domestic origin and available in large quantities, it is, of course, much cheaper than feldspar. The feldspar used by the English pottery trade goes chiefly into brick glazes and vitreous floor tile bodies, very little being employed in white ware bodies. In this respect, English practice is the reverse of American practice.

The British market for feldspar is supplied practically entirely by Scandinavian, though there is a small production of domestic spar, some of which may also find its way to the pottery trade. The Scandinavian deposits are situated close to tide-water and can be worked cheaply. Small vessels that carry coals to Scandinavian ports load up with feldspar at the mines along the fjords and carry it to Runcorn (the head of Mersey navigation) where they discharge into barges. These bring the spar by canal to the Potteries and in this way, freight charges are reduced to a very low figure. The quality of No. 1 Canadian and No. 1 Scandinavian feldspar is about equal, and provided that Canadian spar could be laid down in England as cheaply as the Scandinavian, the trade would no doubt be willing to use it.

To meet Scandinavian competition at the present time, Canadian feldspar would have to be laid down at Runcorn at probably about \$13 per long ton. Since the Atlantic freight is now in the neighbourhood of \$6, this means that the spar would have to be put aboard Montreal or other port for \$7 per long ton, a figure which can hardly be approached by any of the inland producers.

The feldspar deposits of Norway and Sweden are regarded as capable of supplying virtually the entire European market, both immediate and prospective. Cheap water power, also enables the spar to be ground economically at point of origin, and considerable quantities of Swedish-ground feldspar are imported into Great Britain. While expressing themselves as completely satisfied with the quality of Canadian spar, most of the firms interviewed were of opinion that its cost laid down at the Potteries could hardly permit of any competition with Scandinavian spar.

Owing to the relatively small consumption of feldspar in England, users buy in small lots only, and there is consequently little chance for ship-load consignments (2,000-3,000 tons lots) being contracted for by the potters' supplies firms. The small vessels bringing spar from Scandinavia can proceed as far as Runcorn, which is a canal-head, and discharge direct into barges. Large ocean steamers, on the other hand, cannot do this but must discharge at a Mersey port, whence the spar would have to be shipped by rail to the Potteries or else railed to Runcorn, and there placed in barges, both measures entailing a considerable expense over the entirely water-borne Scandinavian spar. The potters' supplies houses, which grind for the trade, contract for delivery according to demand and do not carry the large stock that the American grinders do, with their much larger market. Since there are a number of such firms, each one grinds annually a relatively small amount of spar, possibly only a few hundred tons.

One prominent firm's books showed pre-war (1911) c.i.f. Runcorn deliveries of best crude Scandinavian spar at 20 to 25 shillings per long ton, equivalent, at pre-war exchange, to \$4.35 to \$5.44 per short ton. While it may well be that these low levels will hardly be reached again, present quotations are very much below the prices obtaining during the shortage in 1920.

**\*\*** This information regarding feldspar has been published already in the Financial Post, Toronto, and has given rise to some discussion.

It may, perhaps, be added that during the past two years, a number of mineral brokers not connected directly with the feldspar trade, as well as officials of the Imperial Mineral Resources Bureau and of the Canadian Trade Commission, have been actively looking into the feldspar situation, and that the results of the investigations, as communicated to the Mines Branch, correspond closely with those of the writer's own survey.

The question has been raised whether perhaps ground feldspar cannot be shipped profitably to Great Britain. This point has been considered and was taken up with the trade. In view, however, of the great importance attached by the pottery firms to the assurance of quality in feldspar, and the satisfaction hitherto afforded by the present source of supply, it may well be doubted whether the question of importing ground Canadian spar would be entertained at all favourably. A shipment of off-grade feldspar may cost a potter a great deal of money in spoiled goods, and he naturally prefers to be dependent on a local source of supply, from which he can obtain prompt redress in case of complaint. The potters and potters' supplies houses have been associated so long in the feldspar business that it would undoubtedly be a difficult matter to attempt competition.

**Garnet.**—The garnet coming on the British market is chiefly crude lump, which is preferred by the users to sized, ground garnet. This is due, probably, to the fact that the quality of a consignment is more readily apparent from an inspection of lump than of pulverized garnet; that garnet concentrates made from a garnet schist usually contain a percentage of other heavy minerals; and that the manufacturer can grind lump to his varying requirements without being obliged to stock up with a large range of sizes. Hitherto, Canadian garnet has been offered only in sized grades, representing the concentrates made by milling garnet schist. Such concentrates have been offered to the British trade at a c.i.f. price of approximately \$100 per short ton. As against this, crude lump garnet is selling at \$25-\$30 per long ton c.i.f. United Kingdom, with demand light and apparently no dearth of supply. There appears little hope therefore, that Canadian milled garnet can find a market in the United Kingdom at the price demanded.

It may be noted that the suitability of garnet for the abrasive trade depends very largely on the hardness of the mineral and on how it breaks—whether the fragments possess sharp, chisel edges or are of irregular form and exert little cutting power. All garnet is by no means alike in the above respects, and steps should always be taken to ascertain the quality of the material yielded by any newly-discovered deposit before its development is undertaken. Some garnets break down readily on light crushing into very small fragments, practically powder, and it is not practicable, therefore, to make from such material the full range of sizes required by the trade.

**Graphite.**—The British market for graphite previous to 1910 was supplied mainly from Ceylon, which island furnished a very superior grade of plumbago, or crystalline graphite, that was considered essential for crucible purposes. During the past decade, however, increasing quantities of flake graphite have been secured from Madagascar, a French possession, and this grade of graphite has now largely supplanted the Ceylon in the English crucible trade. In fact, one of the most prominent English crucible firms is understood to have

considerable capital invested in the Madagascar field, and to be using Madagascar flake almost entirely. If the latter statement be correct, it effectually disposes of the contention of American crucible makers that a good crucible cannot be made without Ceylon plumbago.

The graphite market in all countries has been in such a depressed state during 1921 and 1922, owing to the immense over-production in all the producing countries during the last year of the war and the accumulation of large stocks, that it is difficult at the present time to gain a correct index of the situation. The English crucible trade, which probably accounts for the great bulk of the graphite imported, is reported as stocked up with both crucibles and graphite, consequently present sales are almost negligible, and prices low. Best Madagascar flake is now offered at about 3 cents per pound, with few takers.

The general opinion is that Madagascar will continue to dominate the graphite market for years to come, and will ultimately supply the world's requirements for crucible graphite. Less and less Ceylon graphite is being used, as Madagascar flake can be supplied much more cheaply and has been found to answer crucible requirements.

None of the firms questioned could offer any immediate encouragement for Canadian graphite in the European market, either for crucible, lubricant or other purposes. The consumption of graphite in Great Britain for purpose other than crucibles and stove polish would appear to be very limited, graphite lubricants and foundry facings being reported as relatively little used. Madagascar graphite can, of course, be employed for these purposes perfectly satisfactorily.

**Mica.**—An important development that may ultimately result in affecting the Canadian mica-mining industry is the discovery within the last two years of important amber mica deposits in Madagascar. The deposits (about which little authentic information seems to be available) are said to be very large. Considerable quantities of Madagascar phlogopite have been coming on the English market, the mica being of very superior quality and the sheets of large size. Little in the way of smaller grades has reached the market, shipments consisting uniformly of knife-trimmed sheets measuring 2 x 4 inches and up. Madagascar mica is hardly distinguishable from the best Canadian phlogopite.

The low cost of mining in Madagascar, due to native labour and to the fact that the rock is stated to be weathered to a considerable depth should enable even narrow veins to be worked profitably, and may result in Madagascar proving a serious competitor in the mica market, more particularly for the larger and higher-priced grades. So far, there has apparently been little attempt to export the smaller sizes or splittings, Canadian sales for these grades being reported as good during the last quarter of 1922.

Discoveries of excellent mica, both muscovite and phlogopite, have been made in recent years in many parts of the world, including Rhodesia, East Africa, Mexico, Brazil and Cochin India, and considerable quantities of well-graded mica from these sources have been coming on the English market.

With respect to ground mica, it appears that ground amber mica does not find a ready sale in England, the principal user of ground mica being the wall paper trade, which demands a very high grade, silvery-white product. This is obtained from an American source,

and is prepared by a somewhat elaborate process, involving wet-grinding. The product commands a high price and is sold at \$1.00 per long ton c.i.f. United Kingdom. Some of the English wall-paper firms are supposed to have installed their own grinding plants to grind muscovite scrap obtained from domestic sources. The resultant product is not as good as the American, and goes into the cheaper grades of paper. One of the principal markets for ground mica on this side of the Atlantic is the prepared roofing trade, but relatively little of this material is made or used in Europe.

**Talc.**—Relatively little talc is used by the paper trade in Great Britain, its place being taken almost entirely by china clay, which is obtained from Cornwall and is much cheaper than talc. The talcum powder trade is a very limited one, relatively little being made or used. The paint trade also uses very little talc.

Most of the talc imported into Great Britain is of French, Italian or Indian origin, the raw material being essentially steatite, and grinding to a powder possessing good colour and high slip. Some Norwegian talc, also, is used. The Indian steatite is imported in block form, and is used for lava purposes—gas burners and the like. Lava is also prepared from high grade powdered talc, which is pressed into block form (so-called 'synthetic lava'). Some very good powdered talc of Spanish origin has also lately appeared on the English market. Canadian talc, from the Madoc district, has been imported in small amounts.

The total consumption of talc in Great Britain is small. Little or no block or slab soapstone would appear to be used. Samples of the grade of talc required by the English market would indicate that the Madoc talc is inferior in slip, and that from the Eastern Townships in colour, to the Italian and French talcs now imported. Brokers state that the supply of talc from Italy, France and Norway is more than adequate to satisfy British trade requirements. Norwegian talc, suitable for the rubber and paint trades, sells at \$27 per long ton c.i.f. United Kingdom, while the best Italian talc fetches as high as \$63 per ton.

### BALL BEARINGS IN MINES

In a paper recently read before the North of England Institute of Mining and Mechanical Engineers, the striking economies resulting from the use of ball bearings are discussed.

From figures compiled at a South Wales colliery a comparison between ball and roller bearings is instituted. The cost of maintenance and repairs for 2000 pit tubs fitted with roller bearings was £7,590 per annum. These tubs were fitted with ball bearings at a cost of £18,000. Allowing an interest charge of 6% on this amount, and including a depreciation charge of 12½%, the total annual maintenance charge was reduced to £2,430.

One great advantage was that one man could handle two or three tubs equipped with ball bearings, whereas he could handle only one roller-bearing tub. The change also dispensed with the use of power on mild down gradients.

Marked savings of power, smoother working, economy of time, and enhanced general efficiency resulted from the introduction of ball bearings.

About 175,000 natives are employed at the Rand, South Africa, gold mines at present, and about 1,200 at the diamond mines.

### PERSONAL AND GENERAL

ROGER A. BURRALL, formerly sales agent for Chalmers and Williams of Chicago, has accepted a like position with John Inglis and Co., Ltd., of Toronto, who have taken over the manufacture in Canada of the Chalmers and Williams reduction machinery.

WARREN H. S. MACFARLAND has been appointed manager of the various companies in the Yukon controlled by the Gold Fields Company of South Africa through its subsidiary, the Gold Fields American Company, of New York. The Yukon companies are the Burrall and Baird Dredging Company, the New Northwest Corporation, and some allied dredging and subsidiary companies operating in the Klondyke region.

J. M. TURNBULL, of the University of British Columbia, addressed the Vancouver Prospectors' Association recently on the subject of their chosen work. This is part of a systematic effort in British Columbia to aid the prospectors by means of competent instruction.

THOMAS J. MACDONALD, formerly manager of No. 10 colliery, Reserve, Nova Scotia, has been appointed manager of No. 24 colliery, Glace Bay.

NEIL A. MACDONALD has been appointed manager of No. 10 colliery, Reserve, Cape Breton. He has been formerly in charge of other collieries of the district, and leaves No. 9 for his new position.

J. MACKINTOSH BELL has sailed for England on business connected with the Keeley Mine, South Lorrain, Ontario.

J. G. SULLIVAN, the retiring president of the Engineering Institute of Canada, gave a very vigorous address on labour conditions to the Institute at its annual meeting in Montreal last week. He pointed to the fact that professional labour leaders are a menace to the peace of the community, and that the Industrial Council plan is a much more satisfactory means of collective bargaining.

H. C. BARLOW has rejoined the metallurgical staff of the Deloro Smelting and Refining Co., Deloro, Ontario. He has recently been on the staff of the Mining, Chemical and Metallurgical branch of the Dominion Bureau of Statistics.

The shipment of Nova Scotia coal by boat, principally to ports in the United States, continues to be brisk. The harbour of Louisburg is now in use, and it is hoped to ship about a cargo a day throughout the remainder of the winter.

The 127th meeting of the American Institute of Mining and Metallurgical Engineers is to be held in New York on February 19th-22nd. Members of the Canadian Institute have received a cordial invitation to attend the sessions, which include a comprehensive symposium on petroleum and gas, several sessions on iron and steel and non-ferrous metals, and sessions on ground movement and subsidence, breakage and heat treatment of drill steel, industrial relations, metallurgy and general mining topics.

The use of liquid oxygen, absorbed in charcoal, as an explosive in mining is creating a decided interest in mining circles. It is safe, both to manufacture and to use, and experiment has demonstrated that its power is about the equivalent of blasting gelatin. Results from its commercial use in Germany and in Mexico appear to demonstrate that it is more economical than the ordinary explosives.

# News and Comments

BY ALEXANDER GRAY

## *Alienated Affections, or What?*

Two of the strongest groups of oversea capitalists have joined American confrères and are about to restore the Comstock country to at least some of its pristine glory.

Hallowed be the name of Comstock!

Certain sections of Canada are sensitive about this new move, and will not concede that this adolescent Dominion is either unprepossessing, unreasonable or immodest.

It would not have been so disconsolatory, though, if the Consolidated Gold Fields of South Africa through its American subsidiary and the National Mining Corporation, both London institutions of wealth and influence, had bigamously wed a romantic relic within the age limit. Both are vigorous, with lusty progeny seated over the spheres. They are allied, of course, with the New Comstock Merger, capitalized at \$20,000,000, and while the family connection is venerable and Comstock is a name to conjure with there are those who think the strain could have been improved by a match hereabouts. However, the chances are that the antenuptial terms must be attractive and the only thing to do is to wish the international alliance the gayest sort of a joy ride.

None the less is it noticeable that there is a dissentient fraction in Canada who would have protested the bans. To see so much money and influence, hereditary charms and virility, linked in what they regard as rather unholy bonds, is rather trying to the pride and the patriotic emotions of Canadians, who really could do with a portion of what the London corporations have derived from their many notable and diversified industrial ventures. So, it is within the proprieties (though rather late) to convey regrets that the "Gold Fields" and "National" gave Canada the mitten. There had been advances through Mr. Frecheville and Mr. Tyrrell, which never reached the concrete proposal stage, not even when a flank movement was attempted incognito to elope with the Hollinger.

Somehow, and as a rule, London groups of great money-getting capacity either served the frappé or would not play with what they regarded as a "cold deck". What London took in the past twenty years, almost without exception, in the way of Canadian mining properties, was something a sea voyage could not invigorate; this, notwithstanding resident representatives with watching commissions, or New York connections.

Supposedly, the corporation created by Cecil Rhodes and so ably presided over by that Prince of Sportsmen, Lord Harris, and the more recent but hardly less consequential National Mining Corporation, directed by Messrs. Guedella and Agnew, and among others, our own Sir "Mike" Edgar, Bart., pursued their policy of preferring another Anglo-American undertaking, of which there are a number.

This is rather akin to the Mustard Gas, as affecting Canada. We have a miscellaneous array of magnates now, including Sir Binden Blood, a Knight of Pinner's Hall, Col. Grant Morden, and have exchanged the Bir-

go, Davidson, Aladdin, Herrick (in part) with others too numerous to mention in polite company. As another insufficient offset to the London participation with Canada that is sought, it is to be noted that the Guggenheims, United Fruit magnates and various American organizations, are cosily and profitably devoting themselves to British Columbia and Northern Ontario areas.

This American support minimizes whatever unjustifiable heartburnings there are, over the neglect of our mineral areas, even though it does not palliate the frigidity displayed by London and South African capitalists. It is unsatisfactory and undesirable to have the World Metropolis askant as to the real opportunities in Canada or predisposed toward "market deals" with "jobbers" in the leading roles. What share-holdings in prosperous Canadian mining enterprises London may now retain, is more in the nature of a compliment than it is a demonstration of confidence.

Doubtless the Gold Fields and National Mining Corporations, with their organizations, might have taken Canada more kindly and more seriously, were it not for an incompatibility of terms, vendors not infrequently declining to recognize the right of discriminating capital to decide the main features of these terms. On the other hand, London romped with most of the claims Hollinger now includes, did something worse with Kirkland Lake, retained its Lake Shores, wriggled out of Rea, induced the Imperial Government to guarantee the premier securities of a nickel company that is not functioning, declined the McIntyre, scrapped the Northern Ontario Exploration and Porcupine Development Companies — and now has Northern Tisdale and Matachewan!

Where the blame rests for the inability of Canada and London to get together, is for the parties of the first and second parts to explain. It is notable that Dr. J. M. MacLaren of the National Mining Technical Committee was one of the very first to accurately diagnose Porcupine. Messrs. Meyersbach and Marriott of Central Mining and Investment, the "Corner House", intimated that one of the groups of claims now incorporated in Hollinger Consolidated might be acceptable. Hollinger owners as delicately intimated that their ideas of value might not harmonize with those of this casual proposal, so it might be better to await developments. Dr. Simon was one of the earliest international authorities on the Porcupine field. He regarded the Rea definition as about the finest there was. He also unceremoniously condemned the Feldon claims, situated in the Foley-O'Brien-North Dome bailiwick — which may not have been so far wrong, at that.

This is not rancorous reminiscence. It has been a source of wonderment why the best-advised London mining groups have failed to participate in the Canadian developments; for James H. Curle, who carries weight with London, now proclaims that the most attractive gold fields in the world are those of the North Country and that they will continue so for the next twenty years.

The Mining Corporation of Canada and the Keeley are London controlled. Both had years of sorest travail. Beginning with the Townsite and those grotesque royalties imposed by the Temiskaming & Northern Ontario Railway, London elected not to make a profit out of ground that was maltreated until the Watsons, all three of them, arrived to direct and to operate. That the Mining Corporation achieved success is a tribute to the technical management, to the Canadian Directors, and to Cobalt. Of the Keeley, it is to be said frankly that it was foredoomed to the failure that overtook it before it was salvaged from the hands of the liquidator of the Farmers' Bank. Producer gas engines and the Welsh coal that came all the way to South Lorrain, "The engines 'ad to 'ave it"—never made the Keeley what it is, at the end of more than a decade of supposed operation. The correct judgment of J. MacKintosh Bell, and persistence of his principals, who are to be commended as an exceptional London control, enabled the Keeley area to assert its merits. Juxtaposed was the "brain storm" of "Black Jack", who lumped the Silver Queen and the Chambers-Ferland, and fathered the Aladdin, the avowed intention being to "show these wise 'Johnnies' that Cobalt is a deep Camp".

If London has found Canada too exacting or impossible, there are two sides to the story. Professor Frecheville, accompanied by Mr. Tyrrell, was in Porcupine before the railway. We saw him hit the trail—that awful mud route—from Kelso one sloppy morning. Mr. Leggett knew the Hollinger in detail in the earliest stages of its development. Max Francke, Government Mining Engineer under the Kruger régime, and subsequently a managing director in South Africa for Goerz & Co., personally investigated Porcupine. H. H. Webb of the Consolidated Gold Fields and his brother Louis, as well as W. Keene, had first-hand information. A roster of the prominent visitors is superfluous. More recently, when British Columbia had a force of American engineers following up the Premier Gold Mine development, London was represented by proxy. Yet the Selukwe is said to have the Premier extension.

Admittedly there is no sentiment in business, more particularly in mining. We desire London support and offer a share in the business. Canadians have money in Mexico and the Latin Americas. Perhaps they wish some of it were within reach. The West Indies and elsewhere have Canadian capital that could be advantageously employed in Canada. It is the prerogative of the wealthy to exercise discretionary rights, just as it is the privilege of the Gold Fields and National Mining to be jointly concerned with Anglo-American enterprises of magnitude, large enough for the largest, as it were.

No harm, however, will come at this juncture (when Canada is almost over-optimistic about its numerous mining fields and seeks capital) from attaining to a clearer conception of the situation as it exists. It is most opportune to confirm what the recondite H. G. Wells in "The Undying Fire", made Dr. Barrack maintain,— "Telling the truth is the very latest triumph of the human mind".

All repinings aside, it appears Charles V. Bob, a New York mining engineer, one of a group of business men acting as Comstock revivalists, was instrumental in having The Gold Fields American Development Company and The National Mining Corporation take a majority interest and assume the management and development of "fifteen properties controlling 11,116 feet or about two miles of the Comstock and other lodes".

Mr. Bob is "convinced that deposits of gold and silver which it was unprofitable to try to extract in the past, may be taken from the ground with modern methods employed on a large scale". A plant in operation at "neighboring properties" is "producing \$10,000 worth of gold a day".

Cash paid in on January 8 "plus that arranged for in the contract" with the incoming factors, amounted to \$3,485,000. No doubt the whole situation was thoroughly threshed out. Gold Fields Engineers would not be such if they did not know their business. Messrs. Amos F. Keene, Francis de M. Cunynghame and James Ronaghnam are on the Board for the British interests. The area is large and the \$20,000,000 capital has corresponding scope. Frederick R. Weeks is engineer-in-charge. The project is "all set", vendors evidently having been liberally provided for, the vendees always being able to look after themselves.

It remains for Canada to effect a rapprochement with London and its real Mining Groups. Those Groups have the money and the capacity to get more. They will learn that Canada is ready-made by natural creative forces, but they thoroughly understand that ready-made mines either are not for sale or are subject to keen competition. Concessions are essential on the part of those with substantial prospects, who might take a chance with investors who have vast mining interests and do not have to make stock distributions at ruinous discounts.

#### *Death of Henry Melville Whitney*

Daily newspapers of Canada (and elsewhere for that matter) have been singularly remiss in their comments upon the career of Henry Melville Whitney who died on January 26, at Boston, at the age of 84.

No individual did more for the Asbestos Industry, than did the deceased. He was one of its most optimistic pioneers. Yet no reference has been made to that fact. Perhaps he did not foresee the future of his handiwork, but he realized the economic worth of the unparalleled asbestos deposits of Quebec and if he did not profit to the fullest extent therefrom, the honors are his none the less. Even after he had co-operated in the standardization of the Asbestos Industry, there was an inexcusable lack of appreciation of the services he had rendered not only to Thetford and Black Lake but to the Maritime provinces, where he fathered the organization of Dominion Coal and was instrumental in obtaining a participation in the Wabana Iron Fields without which an iron and steel industry on the eastern seaboard would be less in evidence. "No American", it was truly said, "ever did more for Canada", than this New Englander.

Born at Conway, Massachusetts, in 1839, he started as a clerk in a general store. Subsequently he engaged in banking. It was while he was in the shipping business at New York, and was agent for the Metropolitan Steamship Company, trading between New York and Boston, that he became interested in Canada. He was always an advocate of Reciprocity between Canada and the United States, and he made that his leading issue in two campaigns for the Governorship of Massachusetts.

After the organization of Dominion Coal and Dominion Iron, he gave the same force and executive ability to the Asbestos Industry. He was identified with many great enterprises; his errors were those of optimism, notably his determination to find coal in Rhode Island.

Henry Melville Whitney had dropped out of the public eye in Canada. His memory should be preserved and cherished.

# Miners Repudiate "Red" Affiliation

## OFFICIAL STATEMENT OF THE POLICY OF THE UNITED MINE WORKERS OF AMERICA ON THE RED INTERNATIONAL OF MOSCOW

The United Mine Workers of America, which is the trade union of the coal miners, is the first among the great labor unions of this country to take a positive stand and announce a definite policy against the Red International of Moscow and its attempt to destroy the American legitimate labor movement and substitute therefore the principles of Bolshevism. This action has just been taken by the International Executive Board of the United Mine Workers of America, at a meeting held recently. Several months ago the District Organization of the union in Nova Scotia decided to affiliate with the Red International and sent an inquiry to the International office of the United Mine Workers as to the right of the District to effect such affiliation. The matter was referred to a committee of the International union for investigation and report, and the report was filed at this meeting of the board and it was adopted by unanimous vote of the twenty-seven members, representing every District in America. By this action the United Mine Workers of America placed itself squarely on record in opposition to the Red International and all that it represents. The report, which is vigorous in its treatment of the subject, is as follows:

Indianapolis, Indiana, January 11, 1923.

To the International Executive Board,  
United Mine Workers of America,  
Indianapolis, Indiana.

Gentlemen: — We, your committee to whom was referred the communication addressed to the International Executive Board by Secretary J. B. McLauchlan on behalf of District No. 26, concerning the validity of an application by said District to affiliate with the Red International, desire to submit for your consideration the following report of our findings.

Upon an examination of the program and constitution of the Red International, together with resolutions adopted at the last convention of this Organization, we find that among the objects for which the Red International was originally founded, it has for its purpose, first, control, and afterward the destruction of the bona fide trade union movement. The Red International is an outgrowth of the One Big Union, which went through its processes of major development in the north-western provinces of Canada during the year 1918, and like the I. W. W. and kindred organizations that preceded it, the One Big Union was doomed to inevitable failure, so much so, that in the year 1921 the Canadian trade union representatives were able to report to the American Federation of Labor Convention that the One Big Union practically ceased to exist.

An examination of the records of the International Executive Board, United Mine Workers of America, during this period will disclose the attempt that was made by a species of characterless adventurers and spokesmen for the One Big Union who sought to destroy the United Mine Workers of America in District No. 18 at that time.

The Red International is an organization similar in character and make-up to the One Big Union. Its

program and policies being so shaped that it not only sanctions, but in fact urges the workers to resort to street uprisings, mob demonstration, violence, or any other method that they may deem expedient for the accomplishment of their purpose. For example, section 45 of the Red International program reads as follows:

"The fundamental policy of the Trade Unions is the direct action of the revolutionary masses and of their organizations against Capital. All conquests of the workers are in direct proportion to the degree of revolutionary pressure they have exerted. By direct action it is understood every form of immediate pressure of the workers upon the employers and the state, such as: boycott, strikes, street, uprisings, demonstrations, seizure of factories, violent resistance against the removal of goods from factories and stores, and other revolutionary activity leading the working class to the overthrow of Capitalism and consolidating the working class in the Struggle for Socialism. The task of the revolutionary class-conscious Trade Union consists in transforming all the expressions of struggle into an instrument for the social revolution of the working class and its militant training for the social revolution and the establishment of the dictatorship of the proletariat."

Whilst section 54 of this same Organization's program, dealing with the question of collective bargaining, has this to say:

"The belief in the sanctity of collective bargaining propagated by the opportunists of all countries must be met with a resolute and decided resistance on the part of the revolutionary trade union movement. Collective bargaining is nothing more than an armistice. The owner always violates these collective contracts whenever the slightest opportunity presents itself. The respect toward collective bargains only proves that bourgeoisie conceptions are deeply rooted in the minds of the leaders of the working class. The revolutionary trade unions without, as a rule, rejecting collective bargains must realize their relative value and clearly define methods which will abolish these contracts when it proves to be profitable to the working class."

It must be apparent to all who read and think, that this program is in contravention to the policies, customs, practices and laws of the United Mine Workers of America. The membership of our great Organization not only believe in the principle of collective bargaining, but also the sanctity of contracts honorably entered into between the representatives of the United Mine Workers of America and the coal operators. In fact, this is the rock upon which our Union was founded, and in the practice of this policy we have not only made substantial gains in members, but we have also strengthened our Organization in power and influence.

The point of difference between the United Mine Workers of America and the Red International in this respect can be better exemplified by a reference to the following sections of our International Constitution:

"Section 2, Article 2 — To increase the wages, and

improve the conditions of employment of our members by legislation, conciliation, joint agreements or strikes.

"Section 10, Article 20 — Any member or members shutting down a mine in violation of Joint Agreement shall upon conviction by the District organization, suffer such penalty as may be imposed upon them by the respective District organizations."

It may not be amiss to also add that Section 2, Article 14 of the International Constitution, deprives from membership, and also provides other penalties for those of our members holding membership in a dual organization not affiliated with the Federation of Labor. It has come to our knowledge that the Red International is, in the estimation of the American Federation of Labor, a dual organization. Therefore, in accordance with the provisions of Section 2, Article 14, those of our members holding membership in the Red International will be required to pay the penalty provided in this Section, which reads as follows:

Mine managers, top foremen, operators' commissioners, persons engaged in the sale of intoxicating liquors and members of the Civic Federation shall not be eligible for membership.

"Any member accepting membership in the Industrial Workers of the World, the Working Class Union, the One Big Union, or any other dual organization not affiliated with the American Federation of Labor, or membership in the National Chamber of Commerce, or the Ku Klux Klan, shall be expelled from the United Mine Workers of America, and is permanently debarred from holding office in the United Mine Workers of America and no members of any such organization shall be permitted to have membership in our Union unless they forfeit their membership in the dual organization immediately upon securing membership in the United Mine Workers of America. Any member of the United Mine Workers of America who accepts office in any dual organization shall be permanently expelled from the United Mine Workers of America, unless reinstated by the International Executive Board."

Toward this union-wrecking movement the usual sentiment within the great and genuine trade unions is regret that anywhere working people can be found so woefully deficient in the knowledge of trade unionism that they will blindly follow the false teachings of the propagators of such movements. Invariably from their beginnings mushroom organizations of this kind are doomed through their faults of intention and organization to dissension, disruption and destruction. With the passing of time, less and less excuse exists for anything of their nature being brought into existence. Impatient resentment at social wrongs may prompt wild attempts for the abolition of capitalism. Organizations like the Red International may proclaim world happiness through the abolition of collective bargaining, or the inequitable wage system, but it remains for the trade union movement to continue its work with unflinching and direct practicability. It proceeds in safe steps from accomplishment to accomplishment as necessity develops, naturally one step after another. It takes no leap in the dark. It is our purpose to continue the onward march of progress to greater and better days for the United Mine Workers of America through the safe, sane, orderly and lawful methods of the American Labor movement. Our Organization has brought to its members notable and beneficial results, and in the performance of those

duties it is destined to ever go forward. We cannot subscribe, give comfort, or sympathy to the promotion of an Organization, whose chief claim to fame lies in its attempt to destroy institutions such as the United Mine Workers of America.

It is the decision of your Committee that no unit affiliated with the International Union, United Mine Workers of America, can in conformity with the constitution of our Organization, affiliate with the Red International. We would therefore recommend that District No. 26 be required to withdraw their application for affiliation with this Organization, and providing they refuse to comply with the decision of the International Executive Board on this question and affiliate with the Red International, that the autonomy of District No. 26 be suspended, the International Organization assume control of the government of the affairs of that District, and this status be maintained until it has been fully demonstrated that it is the purpose of the membership of District No. 26 to comply with this ruling.

### METALLURGICAL WORKS IN CANADA

The Mines Branch, Ottawa, has published its revised list of metallurgical works in Canada. This includes iron blast-furnaces, manufacturers of ferro-alloys, steel furnaces, rolling mills, nickel-copper smelters and refineries, copper smelters and refineries, lead smelters and refineries, tin smelter, zinc reduction works and refineries, aluminium reduction works, antimony smelter, magnesium reduction works, silver-cobalt-nickel smelters and refining works, Cobalt district customs concentrators and reduction works, and British Columbia customs concentrators. The Mines Branch, Division of Mineral Resources, Ottawa, states that one of the objects of publishing this list is to correct and keep up to date the files in their office, and ask that additions and corrections be sent in to them.

### BOOK REVIEW

YEAR BOOK OF THE SOUTH AFRICAN MINING AND ENGINEERING JOURNAL — Johannesburg, South Africa.—402 pages, price 10s. 6d.

This volume is called the "£1,000,000,000 Special Number", as the year 1922 marks the production in South Africa of mineral wealth of that huge value. Gold has contributed almost three-quarters of this amount, and diamonds almost the other quarter, coal and copper being a poor third and fourth at £54,000,000 and £23,000,000 respectively. It is noted that South Africa has provided 55.9% of the world's total production of gold, the United States, 15.3%, Canada 5.6%, Australasia, 5.0% and other countries lesser amounts. The Rand ore reserves show stupendous amounts of gold still to be extracted from the reefs, most of it of paying grade under present conditions.

Of growing importance to South Africa are the outlying mineral districts, and these are well described in the volume. The chromite and asbestos of southern Rhodesia, the Union's various important coal fields, the budding iron and steel industry and the diversified mineral products of the important Katanga region are all dealt with.

This is a valuable reference work on South African mining.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**COBALT.**—The first round drilled at the Beaver, after work was started on the property, resulted in the discovery of a 3-inch vein of high-grade. The Beaver has been shut down for several years, and has recently been re-opened after the Coniagas has arranged to finance and operate the property on a profit sharing basis with the Beaver.

**KIRKLAND.**—Recent results in the Kirkland Lake camp indicate that several consolidations may take place. It is announced that the Buffalo interests who, about a year ago, entered into an arrangement with the Kirkland Lake Proprietary for the development of the Sylvanite property on an equal basis, have arranged to purchase the whole of the property. The deal is an important one, running into several hundred thousands, the purchasers being interests connected with the Wright-Hargreaves. The Sylvanite lies between the Tough Oakes and Wright-Hargreaves properties, and is the most important undeveloped property in the camp. It is logical to assume that when the property is developed to the stage where a mill is required, it will probably be amalgamated with the Wright-Hargreaves. The Sylvanite shaft will be sunk below the 500-foot level, and a larger mining plant is to be installed.

The Wright-Hargreaves management is already talking about increase the mill capacity, and if developments to the 1000-foot level compare with those in the upper levels, the enlargement will be proceeded with. The shaft is now down to the 900-foot level, and levels are being opened up at 750 and 850 feet. The ore is averaging \$12.00 per ton, and substantial profits are being made.

A report of the Kirkland Lake Proprietary for the year ending June 30th, 1922, shows a recovery of £4,105, against expenditures of £29,800. The mill was only started in the latter part of the fiscal year, and between the end of June and the end of November \$75,000 in gold was produced. The directors state that a representative of the company is in the United States negotiating with American interests for the sale of the properties. The prospective purchasers of the Tough-Oakes and the Burnside are understood to be the Continental group.

Further details regarding the purchase of the Orr property by the Teck Hughes do not show the deal in quite as favorable a light as was originally announced, but, notwithstanding, indicate that the Orr was taken over at a price which will be satisfactory to the Teck-Hughes. Negotiations have been under way for several months, and the Teck-Hughes officials are satisfied with the terms. It was originally announced that the consideration for the Orr was to be 600,000 shares of Teck-Hughes stock, and this stock was to be obtained by increasing the capital from 4,000,000 shares to 5,000,000 shares of \$1.00 par. It is now announced, however, that the 600,000 shares of Teck-Hughes will purchase the 1,050,000 shares of the Orr Gold Mines belonging to Conrad E. Wettlaufer and associates of Buffalo. Arthur E. Moysey & Company own 730,000 shares, and are to receive 35 cents a share in cash. There

are an additional 61,000 shares in the hands of the public, and the Teck-Hughes will be authorized to purchase these at 35 cents. This will represent a total cash outlay of approximately \$275,000, in addition to the 600,000 shares of Teck-Hughes stock. A meeting of the Teck-Hughes is to be held on February 1st, at which the necessary by-laws to cover the different purchases will be ratified. The Orr Gold Mines own a considerable acreage adjoining the Teck-Hughes, and the main vein of the Teck-Hughes passes through the corner of the Orr property. Ore reserves on the Orr property are stated to be \$2,000,000, and as the vein dips to the South it will have an increasingly greater length in the Orr property as greater depth is attained.

Shareholders of the Bidgood Gold Mines will meet on February 1st to consider, and if deemed advisable, to ratify a by-law increasing the company's capital from \$2,000,000 to \$3,500,000. Of the new stock 625,000 shares are to be used to purchase two adjoining claims, and it is understood that the additional stock will be sold to finance development.

**BOSTON CREEK.**—It is understood that English interests have offered to purchase 1,600,000 shares of the Baldwin Gold Mines at 2 shillings a share. This would include 400,000 shares of treasury stock and would mean approximately \$180,000 for the treasury. While it is not stated, it is assumed that this is an option and not a contract to purchase. Some good ore was recently found on the Baldwin, but as far as can be learned there is nothing to justify any such price as stated above, except on an option basis with time payments.

A. D. Miles, representing English interests, is commencing diamond drilling on the Walsh claims in Catharine Township. The option on the Skead Gold Company's properties has been dropped, and the drills have been pulled off.

A short report of the Kirkland Gateway Property indicates that favorable results have been met with. The company is calling for tenders to sink the shaft from the 265-foot level to the 500-foot level.

**PORCUPINE.**—The report of the McIntyre for the quarter ending December 31st, shows gross recovery of \$608,000, as compared with \$586,000 for the preceding quarter. The total recovery for 1922 was \$2,140,000, which constitutes a record in the history of the company. As the output for the first six months was \$945,000, a substantial increase in the latter part of the year is indicated. Due to heavy development charges, which includes a good deal of shaft sinking, profits for the last quarter show a slight decrease as compared with the quarter ending September 30th, and amounted to \$260,000 against \$268,000. The shaft is now down to a total depth of 2300 feet, which is the deepest in the Porcupine district.

The Dome report for the nine months ending December 31st, shows gross profits of \$1,975,000. After deducting \$94,000 for estimated Dominion Taxes and \$421,000 for depreciation of plant and mine exhaustion, the net profits amount to \$1,460,000, which is considerably in excess of dividend requirements. The directors have announced that next July a dividend of

\$1.00 a share, on the new stock, will be started, and to insure a continuance of this dividend, a special fund, called the "Dividend Assurance Fund", with \$1,003,000, has been created. This will be added to until it amounts to a full year's dividend. The balance sheet shows a strong cash position, and the amounts included, Bonds — \$481,000, Dividend Assurance Fund — \$1,003,000, loans on call — \$1,119,000, inventories — \$300,000, Bullion in Transit — \$62,000 and cash — \$329,000.

The Goldale bungalow and cook camp were burned down a few days ago. Five men were sleeping there and they had a narrow escape from being burned to death. Among them were Harry Kee, the manager and T. H. Rea and all of them had to get out in their night clothes. Three of the men received minor cuts and burns and had to be taken to the hospital. The fire started from an overheated floor.

### NORTHWESTERN ONTARIO

**PROSPECTORS CLASSES.**—Dr. W. L. Goodwin, mineralogist of the Ontario Department of Mines, Toronto, is at present holding Prospectors' Classes in the rooms of the Port Arthur Chamber of Commerce. Morning and afternoon sessions are being held, at which a thorough grounding in the principles and practice of prospecting for minerals is given, followed each evening by an illustrated lecture by Dr. Goodwin, where a complete set of lantern slides are thrown on the screen and fully explained to the students and audience by Dr. Goodwin, with his well known facility for imparting geological information. Both the classes and lectures have been well attended, but not quite up to what might be expected in a country abounding in mineral wealth, the possible mineral areas of which are constantly being extended into new fields that offer the greatest inducement for well equipped prospectors to carry on intensive and intelligent prospecting. The classes and lectures will be concluded on the 27th, and a similar course will be commenced at Fort William on the 29th, under Dr. Goodwin.

**RED LAKE.**—News of the north has just been brought in by Findlay McCallum, of Fort William, who has been prospecting in the Red Lake district in northwestern Ontario for a Winnipeg syndicate comprising J. E. Botterell, S. E. Richards, and W. P. Fillmore. Mr. McCallum reports interesting finds of both silver and copper. Supplies will be taken in during the winter over the trails from Sioux Lookout, a distance of 175 miles to the claims. Considerable staking has been done; one report says 1000 claims have been staked, and a large majority of them recorded, with every prospect of this area showing great activity during the coming summer.

**IRON ORE COMMITTEE.**—Mr. G. S. Cowie, representing the Ontario Iron Ore Committee, met the Port Arthur Chamber of Commerce on the 16th, when a strong memorial was presented covering the various iron ranges in northwestern Ontario, outlining the character, quality, and possible tonnage of the different deposits, together with the modes of beneficiation applicable to each, and, pointing out the necessity for the development of our iron ores throughout the Province, and the need of some Government assistance to bring about the establishment of a permanent iron ore industry within the Province. The memorial presented to Mr. Cowie asked for a straight cash bounty of not less than fifty cents per long ton, on the finished prod-

uct. It was the considered opinion of the Chamber that this form of assistance is preferable to any other, for the reason that the treatment the ores must be subjected to, to fit them for furnace use, vary so greatly that if the Government undertook to finance beneficiating plants, the number of such plants that would be asked for would run into prohibitive figures, whereas a cash bounty would only involve the Government to the extent of the bounty given on each ton of finished product, the whole risk of production being taken by the iron ore operators.

### NOVA SCOTIA

**THE RADICALS RECEDE?**—If the Executive of District No. 26, United Mine Workers of America have any desire to recede from the position they took when they decided to join the 3rd International, Moscow, they have now a splendid opportunity. The Cumberland and Pictou county miners have always openly opposed this unspeakable yoking together and are more decided in their protests today than ever. Besides, there has been a cooling of the ardor of a large number of the Cape Breton "Reds", who upon reflection find they are not ready to give up the time-honored institution of their land and follow strange gods. Indeed, there has been a growing resentment towards those who would beguile them to industrial and social destruction. The silence of the leaders on this question during the past months has been eloquent of unexpressed doubt as to the prudence or propriety of going through with the job.

And now the International executive thunders its anathema on ail, even the whole district, should the application to the "Russian Reds" not be withdrawn. There is no mistaking the language and tone of the "International Mandate". The district will lose its authority, and be governed by officers appointed by International Headquarters should it fail to respond to the instructions sent to Secretary J. B. McLachlan, to keep clear of Moscow affiliations.

**SHORTAGE OF SKILLED MINERS.**—The output of the Dominion Coal Company having increased during the last six months, it was found necessary to increase the number of skilled men at the coal face. Application was made to the Government by the Company for permission to have more men supplied. The President of the United Mine Workers opposed this application on the grounds of low pay and other such reasons. This is the men who, when the agreement was entered into last August, expressed the wish that the coal industry would have a good year.

If the coal output is to increase it can only do so by having the necessary supply of skilled miners. The native supply of Nova Scotia miners is exhausted and others must be found outside the province. Without additional skilled workmen there can be no large increase in the output of coal.

Increased output means lower costs and therefore larger sales. At a time when the Coal Company is making gigantic efforts to extend the scope of the market it would be unwise on the part of any Government to put any obstacle in their way. All the Nova Scotia collieries are working steadily in the face of the statement about low wages made by President Livingstone, good wages are being earned.

**WABANA.**—Wabana Ore mines report conditions quiet and that they will remain inactive until spring time.

## BRITISH COLUMBIA

**THE B. C. SILVER STRIKE.**—The recent phenomenal rise of shares of the Selukwe Mining Company of Rhodesia on the London market, the advance being from about eight shillings to around twenty seven shillings, is explained by the reported opening up of a new pre-body on the Portland Canal holdings of a subsidiary concern, the B. C. Silver Mining Co. Of this development it is authentically stated that a twenty foot vein of fair ore in fissures in quartz porphyry has been cut. This, no doubt, is an extension of one of the Premier Mine fissures, according to authoritative information. The news was cabled to London and the effect was quickly registered in market quotations on the stock of the company. The demand was accelerated by the recent announcement of the dividends being paid by the Premier Mining Company, which is operating in the district in which are located the Selukwe holdings.

**PORTLAND CANAL.**—The second payment has been made by A. B. Trites, vice-president of the Premier Mining Co., and his associates on the Big Missouri and Unicorn groups of mineral claims, which they have bonded and which are situated in the Portland Canal Mining Division. This means that development will be continued next summer. Last year a force of about 35 men was employed on the Big Missouri, the work being largely exploratory and prospecting.

A rawhide trail has been constructed from the Fish Creek property of the Amercian Mining & Milling Co. to the Salmon Valley road and already substantial shipments of high-grade ore have been made via this route to the tidewater town of Hyder, Alaska. A Sullivan compressor has arrived and is being taken over the winter trail to be installed at the mine.

The Silverado group of mineral claims, situated at an elevation of 4,000 feet on the mountain east of the town of Stewart and above the mouth of the Bear River, has been taken over on a working bond by the Silver Bell Mining Co., of Seattle, Wn.

The demand for a ready means of quickly performing preliminary development work on promising prospects in the Portland Canal Mining District has led to the organization of the Hetu Mining Contractors Ltd. Their stock in trade will be portable mining machinery, including portable compressor equipment. Their officers are mining men of Prince Rupert, Alice Arm and Stewart. Already one of these plants is in the field and others will be provided as orders are received.

**PIONEER MINER DEAD.**—R. T. Ward, prominent in British Columbia mining circles through his association with the Bullion Mining Co. of the Cariboo, died on Friday, 19th January, at Vancouver. He came to this Province in 1866 and was among those who stampeded to the Cariboo in search of gold. His interest in the mining possibilities of the great interior plateau never ceased. With some associates he acquired the holdings of the Bullion Placer Mining Co. Title, however, was disputed by John Hopp, another Cariboo miner. The case was fought through all the courts, victory finally going to Mr. Ward in the Privy Council. Steps, it is understood, have been under way with a view to the re-opening and the placing of these famous leases on a productive basis.

**TELKWA.**—New York financial interests are reported to be backing T. E. Jefferson, of Telkwa, in the development of fifteen gold bearing mineral claims situated on Dome Mountain. The properties are about twenty miles north of the town of Telkwa.

**CARIBOO.**—A mild winter is being experienced in

the Cariboo, which is proving a boon to Cedar Creek miners. The work of the latter, it is stated, is being carried on without interruption and several shipments of gold have been made recently. An important quartz discovery is reported near the town of Clinton upon which development will be started as soon as the snow leaves.

**YMIR.**—The Goodenough fraction and several adjacent claims, Wild Horse Creek, near the town of Ymir, have been shown to be promising prospects and the properties now are Crown Granted. The ore-shoot of the old Ymir Mine is said to have been found in these claims and important developments are expected in the course of the next season's work.

**KOOTENAY.**—Harold Lakes, superintendent of the Selkirk Mines Ltd., reports that ore is being sacked at the Kootenay Bell Mine, one of the group controlled by the company, for shipment to the Trail Smelter. The construction of a tramway to the Nugget Mine mill is planned to facilitate transportation of ore for treatment.

**TRAIL ORE RECEIPTS.**—Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co., for the first two weeks of January totalled 18,401 tons, 836 tons being received during the first and 9965 tons during the second week. Receipts for the second week were as follows: Black Rock (Zinc) Northport Wn., 242; Knob Hill (dry ore) Republic Wn., 310; Lone Pine (dry ore) Republic Wn., 178; Molly Gibson (lead), 77; Paradis (lead), Invermere, 88; Quilp (dry ore) Republic, 236; Sally (lead), Beaverdell, 35; Silver-smith (lead), Sandon, 269; Sliversmith (zinc), 48; Surprise (dry ore), Republic, 209; company mines, 8899.

**NELSON.**—The properties of the California Mining Co., situated near Nelson, which reverted to William Moore through failure of the J. R. Cassin Company, Spokane Wn., to make a final payment, are expected to be active in a short time. Ernest Watson and associates have bonded the Union group of three claims. Further development is to be done in the old workings of the Union Mine and a considerable quantity of ore on the dump is to be sorted and shipped to the smelter. Mr. Watson is having the road opened for the transportation of supplies. The California group of claims is under option to James Dinsmore, of Seattle Wn., whose inspection of the property is reported to have satisfied him of its possibilities.

A new corporation has been formed bringing under one management the Burrall & Baird Dredging Company, the New Northwest Corporation, the Canadian Klondike Power Company and several allied companies operating in the Klondike gold fields. These companies control about 100 miles of the old Klondike gold creeks which will be worked by dredge and hydraulic. It is estimated that there are twenty years of work ahead. There are three dredges and many hydraulic plants in operation at present on Dominion Creek and in the Klondike valley. Warren H. S. Macfarland has been appointed general manager succeeding Frederick P. Burrall, who has resigned to accept another important position connected with American mining interest. He, however, will remain as advisory engineer to the Klondike concern.

Trial of a carbonizer, developed by the Bureau of Mines, Washington, to carbonize Western Canadian lignites, will be made, and, if found satisfactory, will be installed to replace the carbonizers developed by the Lignite Utilization Board at Bienfait, Sask. This was decided at a meeting recently in Winnipeg of Provincial and Federal Government representatives.

Three million horsepower of electrical energy was developed from Canada's waterfalls during 1922, of which 1,330,000 was in Ontario, 1,100,000 in Quebec, 310,000 in British Columbia and the remainder distributed between Manitoba, Alberta, Nova Scotia, New Brunswick and Prince Edward Island. It is estimated by the Federal Water Powers Branch that the horsepower development per 1,000 of Canada's population, is 337, the total capital invested in the development \$620,658,731, and the estimated revenue is \$81,600,000.

Brazil, with thirty million inhabitants and an area as large as Canada, has only 20,000 miles of railway. The United States, with a slightly smaller area, has 250,000 miles of railway. Brazil's hinterland, back from the coast and the chief navigable rivers, is but little developed and has only a sparse population.

In the state of Victoria, Australia, there is a dearth of waterpower for the generation of electricity. Recourse is being had, therefore, to the beds of brown coal that occur at the surface in the Morwell field, as a source of cheap power. This fuel contains 50 per cent. of water and has a calorific value of 4,800 B. T. U's. The coal will be "mined" by steam shovel and burned under boilers to make steam for turbo-generators. The fine coal, which is not suitable for firing direct, will be briquetted, the briquettes to contain 12 per cent. moisture with a calorific value of 9,300 B. T. U's. It is intended to use these briquettes also for domestic and general industrial purposes. At present about 1200 men are employed in establishing this vast undertaking.

The drop in the price of copper from war-time levels has paralyzed the Australian copper industry, though it is founded on comparatively rich and abundant ores.

The director of the United States Mint makes a preliminary estimate of the gold production of the United States of America for 1922 as 2,375,019 ounces valued at \$49,096,000. This total is \$971,000 less than the product of 1921, and less than half of the record production in 1915 of \$101,035,700.

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

# There's a Record of Performance back of ENDURANCE GRINDING BALLS

Endurance balls will reduce your Grinding Costs.

The long and satisfactory service they render is an assurance of more efficient and less expensive Grinding operations.

We manufacture Cam Shafts, Shoes and Dies that are equally reliable.

Prompt shipments.

## Canada Foundries & Forgings LIMITED WELLAND. ONTARIO

# What Angle Compound Compressors Will Do for You:

1. Provide a constant, reliable air power supply.
2. Cut in half the floor space devoted to Compressors.
3. Cut in half your foundation and installation charges.
4. Permit ready adaption to any form or arrangement of power drive.
5. Lower your horsepower per 100 feet of air compressed.
6. Operate efficiently at partial loads.
7. In the "twin" direct motor driven units, avoid excessive peaks in the power inflow.
8. Require minimum attendance and repair.

Ask for an "Angle Compound" proposal  
on your new compressor

# FOR COMPRESSED AIR LINES USE CRANE MINE COCKS

**IRON BODY BRASS PLUG  
STEEL SPRING**

**Tested under Air Pressure. Suitable for 125 pounds air pressure and 175 pounds cold water working pressure.**

No. 318 cock is especially adapted for use in coal mines and for other purposes in the operation of compressed air driven machines where it is necessary or desirable to prevent any tampering with the opening or closing.

The spring automatically takes up any wear, thereby maintaining a tight cock, and reducing repairs to a minimum.

No. 319 is intended for general use and can be opened and closed by an ordinary square key wrench. Made in two styles. Sizes  $1\frac{1}{2}$  to 4 inches.

# CIRCO<sup>SM</sup> HOISTS

## *To Meet Your Specific Requirements*

There are certain conditions which any hoist must satisfy to exactly meet individual requirements.

Sometimes these are sufficiently unusual to necessitate the use of specially designed equipment, but in the majority of cases one of the many standard CIRCO Hoists will do the work with little or no changes.

And, up to a certain point, all CIRCO Hoists are built standard so that even when special

units are required they can be furnished with but moderate special manufacturing changes.

When desired, we will be glad to study conditions at your mine and then recommend the size, type and equipment of the hoist best adapted to meet them safely and economically.

This will result in the installation of a machine combining moderate first cost, convenient control, low operating and maintenance charges, to a degree which will reflect favorably upon the operation of the entire property.

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.         | Value.      | Year.         | Value.       |
|---------------|-------------|---------------|--------------|
| 1891 .. . . . | \$4,705,672 | 1906 .. . . . | \$22,388,383 |
| 1896 .. . . . | 5,235,003   | 1911 .. . . . | 41,976,797   |
| 1901 .. . . . | 11,831,086  | 1916 .. . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

THOS. W. GIBSON,  
Deputy Minister of Mines,  
TORONTO, CANADA.

# MORSE CHAINS

A few of the Morse chains in use at the Raymond Lead plant

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.

Write for Booklet

CANADIAN AGENTS

**Jones & Glassco, Regd.**

MONTREAL, TORONTO.

O. W. Ludwig, Plant Superintendent of the Raymond Lead Co., Chicago, says:

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful—and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

**MAKE YOUR Idle Water Power Pay Dividends**

**IMPROVED KINCAID WATER WHEELS DEVELOP ECONOMICAL and EFFICIENT POWER FOR MINES**

The "KINCAID" water-wheels deliver the full theoretical power calculated from a given quantity of water from a stated head.

Using the best materials combined with careful workmanship results in the "KINCAID" being a water-wheel as near mechanical perfection as it is possible to make it. Let us demonstrate its possibilities to you.

*Of all the industrial arts which contribute to the progress and welfare of mankind, we may claim the most important place for mining and its hand-maiden, metallurgy.— R. G. Leckie — 1897.*

### WHAT'S WRONG WITH THE INSTITUTE?

Numerous members of the Canadian Institute of Mining and Metallurgy are asking themselves and others this question, and the diagnosis presents a wide variety of conclusions. The principal point of agreement is that something is wrong and that steps must be taken to cure it.

Any who doubt that something is wrong need only study the facts of the recent election of officers for the coming year—the election is already complete—and their doubts will be resolved. We print the list on another page. It is a notably appropriate council we have elected (or selected) and one that is sure to exert itself to the full of its ability on behalf of the Institute. The regrettable feature is that branches and private members have taken as little interest in their Institute that the election is uncontested. Worse than that, the minutes of Council record the fact that a large fraction of the incoming executive were appointed by council, on account of the failure of some of the branches and of private members to nominate candidates. We are sure that the members of the incoming Council would be much better satisfied had their election been the result of a well-fought contest with worthy opponents. The Institute's elections have fallen flat, and the honour of election has lost much of its former meaning.

One discriminating student of Institute affairs has come to the conclusion that the introduction of the letter ballot and the other features of a highly-organized mechanism have "killed" the camaraderie and the will to work for the Institute that was so notably characteristic of the first fifteen years or so of its existence. It may be that this spirit can be reclaimed only while there is a comparatively small number of members, and that the larger organization with its necessary perquisites has of necessity excluded these former features. At any rate it is more a matter of record that the letter ballot both for elections and for changes in the by-laws has failed to attract interest, since the vote nowadays is even smaller in proportion than was the standing vote in the annual meeting under the old regime.

Our own opinion is that the present case is by no means hopeless. The human element still remains, and

acterized the former activities of the Institute is still available, and indeed is available in greatly increased amount. It is not now being used on behalf of Institute affairs in the degree to which it can be and must be used if the Institute is to fulfil its mission. The incentive due to personal contact and to rousing meetings has to a large extent disappeared, and nothing adequate to the need has taken its place. We have attempted to replace human intercourse with a mechanism, and our attempt has ended in failure. By hook or by crook, we must make the Institute more human and less mechanical, if it is to retain its present grip on the mining industry and regain what it has lost. This idea is, we believe, in the minds of most of those who have grappled with the Institute problem during recent years, though few have formulated it clearly.

What expedients the Institute should adopt in pursuit of this end, we do not presume to decide off-hand. It is hardly possible to return to the conditions of "the good old days". The step must be a forward one. The Secretary's "forward movement" is in the right direction, but it has not gone to the mark. We have suggested that the pursuit of the objects of an exclusively professional society by those now, and in the future, classed as professional members might prove to be the bond of union that now is lacking, as well as an adequate incentive. The Western members would make the whole Institute thus homogeneous by excluding a large fraction of the present membership—a course we consider impracticable as well as inexpedient and unnecessary. Other proposals will, no doubt, be made.

What we must all bear in mind is that any and all attempts to convert the Institute into a smooth-working machine are bound to be detrimental; a machine is not human, and if human interest is lacking, the human beings that constitute the membership will inevitably fall away from its active support. The reading and discussion of technical papers is not enough. Activity in the pursuit of a just cause and its active defence have been the making of many a so-called nation of gentlemen and even nations. A cause worthy of our attention is the protection of our mining industry from frauds and fakirs—a cause the Institute has not of recent years sup-

ported with more than empty words. There is plenty of human activity in such a cause; in fact it is composed of human interests throughout.

We hope that at the Annual Meeting in Montreal a month from now there will be a broad-gauge discussion of this matter that will elucidate the principles involved. The attention of the meeting is more likely than not to be directed to inconsequential details and side issues unless a number of the members take pains beforehand to focus their attention on the main issue. We bespeak the attention to this of all those interested in the welfare and progress of the Institute.

### THE SYMBOLIC AND THE ABSOLUTE

Progress in science implies the continuous readjustment and revision of ideas and ideals.

Take a recent instance. Scientists now have reason to think that graphite and, possibly, the diamond may no longer be considered pure carbon. Researches conducted by Sir William Bragg indicate the probability of graphite being a compound of hydrogen and carbon. This conclusion is based upon recondite study of atomic structure. Not only is this indicative and characteristic of the far-reaching results of modern speculative research but, from the fact that it has an unexpected bearing upon the utilization of coal, it is a remarkable illustration of the utility of the most refined scientific investigations.

This induces introspection. As a foundation for thought we have been compelled to accept certain arbitrary symbols that represent the absolute. As convenient datum points we postulate a number of primary elements, irreducibly minute atoms, absolute zero, final special and dimensional relationships, and admittedly inadequate concepts of energy and matter. Step by step we have outgrown these concepts, have modified them more or less timidly, but we are loth to discard them.

All sciences are advancing and expanding at a rate that is bewildering. "Facts" are sought, and there are ever-multiplying facilities created to aid the seeker. In no fundamental science has there been a more ardent search for ultimate truth, a more persistent rejection of non-essentials, than in geology. And yet geological thought today is still strongly tainted with reactionary ideas. The scholiast, who is also the seiamachist, has far too much to say; the practical geologist has far too little. We accept symbols that are outworn and talk that is talk *et praeterea nihil*. Phrases become formulae, and formulae become sacred. A little irreverent questioning of authority is needed.

Bold speculation is as necessary in geology as in mining. Our tendency to accept a *credo* because it has currency, is something to be guarded against. We need not pull down the temple, but we should ventilate it.

### PROGRESS IN KIRKLAND-LARDER-ROUYN GOLD FIELD

The band of Temiskaming sedimentary rocks extending from Kirkland in Ontario to Rouyn in Quebec, and beyond in both directions, promises to be the centre of mining development activities in the north country during the coming season. Already sufficient of its wealth in gold has been disclosed to warrant the attention of a large number of substantial mining companies and syndicates, and an unusually large number of showings are being carefully examined and developed. Though there is, no doubt, a certain fraction of good ground being withheld from active development by the blanketing tactics of speculators who will neither spend the money required nor concede reasonable terms to others who are ready to spend it, still the district is, generally speaking, in good hands.

In 1910-11, when the eastern part of this area in Quebec was found to be gold-bearing, Dr. M. E. Wilson of the Geological Survey, Ottawa, commenced to map it. The Bureau of Mines, Quebec, also paid some attention to it. For some unaccountable reason both these departments failed to carry on this mapping, though it was obvious that the region held a great deal of promise for the prospector and that what the prospector needed most was the guidance of the geological maps that our pioneers geologists are so eminently capable of providing.

A year ago the need for the geological mapping of this area in Quebec became so pressing and it offered such an inducement for direct service to the mining industry that the Director of the Geological Survey sent in two parties under Dr. H. C. Cooke. It so happened that prospectors in large numbers also penetrated the field, and there is no doubt that this intimate association of geologists and prospectors had its usual fruitful result.

There still remains a large amount of mapping to be done in the new Quebec area before the geologist will have fulfilled the whole of his mission in co-operating with the prospector. Last year's work was merely a beginning, and there is no doubt that the Director of the Geological Survey, as well as the officers of the Quebec Bureau of Mines, have borne this fact in mind when planning for the activities of the coming season. It may be noted, by the way, that the request of some of those interested in the Kirkland field that Dr. Cooke be authorised to make a detailed examination there and thereabouts is singularly inopportune, not only on account of the urgent need of mapping further east in Quebec, but because the Kirkland field has been studied thoroughly already; in fact a new report and a new map are now in course of preparation by the Department of Mines in Toronto. When geologists are so few, a mining community should not ask to have its bread spread with jam on top of the butter!

Looking forward, we can hope with some reason that the new gold district will escape the orgy of speculation that has crippled all, and killed some, of our embryonic mining camps. Prospectors, investors, examining engineers and even promoters seem to be possessed of more of the spirit of sweet reasonableness than ever before. We hope it will prove to be so, and that the end of the next season will show the belt of payable gold veins that commences at Kirkland extended well into the province of Quebec.

#### EDITORIAL NOTES

Our Northern Ontario correspondent records today the progress during January of the new Violet shaft of La Rose Mines, Cobalt. He states that 155 feet 2 inches in one month is a record for Ontario, if not for Canada. The rock of the mineral districts of Northern Ontario is typically hard, so that it is not likely that a world's record will ever be set in those parts. Such a monthly footage as that recorded demonstrates, however, not only the remarkable advances during recent years in the mechanisms and technique of drilling and blasting, but the wonderful durability of the modern rock drill even when up against hard rock.

The phenomenally wide face of ore recently opened up on vein 26 in the Keeley mine, South Lorrain, Ontario, was officially inspected last week, by Mr. Cyril W. Knight of the Ontario Department of Mines. The photograph shows ore of a maximum width of a full five feet, which is said to average 5,000 to 7,000 ounces of silver to the ton. Even a casual inspection of the ore shows that it is amazingly rich. This bulge in the vein is a "freak", and an interesting one. The really important point is that a new ore-shoot, averaging seven inches in width of unusually high-grade silver ore, has been disclosed in a drift for a length of 58 feet, and at last report was still going strong.

At last the Hollinger Mine is assured of sufficient power to permit of its maximum production of gold. The Minister of Lands and Forests in Toronto proposed terms to Hollinger officials last week that can be accepted by the company. The terms include adequate protection of the rights of the numerous other interests concerned — the Abitibi Paper and Power Company, the T. and N. O. Railway, the town of Cochrane, and the people of Ontario. What appeared formerly to be mere obstruction on the part of the government in Toronto is now seen to be principally the uncertainty consequent upon the number and diversity of the interests involved, though the delay in a settlement was undoubtedly prolonged on account of the provincial administration's comparative inexperience in the handling of large financial affairs. However, all's well that ends well, and now we shall see

the Hollinger outdistance all the world's records for gold production.

In discussing "Canadian Iron Ores" editorially in a recent issue, *The Mining Magazine*, London, notes the appointment of Hon. Harry Mills' Committee on Iron ore and continues: "A perusal of the Report on 'British American iron ore resources issued by the 'Imperial Mineral Resources Bureau leaves a gloomy feeling, and arouses something in the nature of commiseration with this new committee with regard to 'the unattractiveness of the duties which they have 'undertaken.' We hope the case is not as bad as that!

#### HISTORY — IV

##### THE FIRST ASSAYER

The first assayer, doubtless,  
 Attended Nature's school;  
 He did his work all cloutless,  
 And improvised each tool.  
 In smelting metals native,  
 It seems a patent fact,  
 Results were qualitative,—  
 They could not be exact.  
 Yes, primitive and simple  
 The first assayer was;  
 No more than any pimple  
 He knew of chemic laws.  
 Yet that he was resourceful  
 I'd freely bet my life:  
 For, not one whit remorseful,  
 The Mother-of-his-Wife,  
 When bone-ash moulds were needed,  
 He slew and burned to dust;  
 Her cries he little heeded,—  
 He had an awful crust.  
 Her tibia he saved it  
 And polished it with care,  
 And with a legend graved it  
 In symbols large and fair.  
 "Eureka!" ran the graving,  
 "I've got the stuff at last  
 For which the world is craving,  
 "The Age of Stone is past.  
 "What weapons I can fashion!  
 "What implements design  
 "For men to do their bashin'  
 "What tribute will be mine!  
 "So, e'en though she was hateful,  
 "That Mother-of-my-Wife,  
 "To her shall I be grateful  
 "Through every day of life."  
 For he had smelted copper  
 From out of weathered stones,—  
 Used a cupel, a whopper,  
 Made out of female bones.

J. C. M.

# Gold and Silver at Schreiber, Ontario

BY P. E. HOPKINS

The mineral deposits of the Schreiber-Duck Lake area were described by the writer in a 1921 publication\* of the Ontario Department of Mines, which was accompanied by a colored geological map. Since that time a silver discovery has been made; hence the writer returned to the area for a few days in November 1922, and reviewed the recent developments, which are here described by permission of Mr. T. W. Gibson, Deputy Minister of Mines. For convenience the accompanying sketch map has been prepared to show the geology and the locations of the working properties.

As shown on this sketch, the gold deposits occur along or near the contact between Keewatin rocks and a large mass of Algonian granite and syenite. The Keewatin, which consists largely of basalt and rhyolite with subordinate amounts of felsite, iron formation, slate and conglomerate, has been intruded by numerous dikes of syenite, granite porphyry, feldspar porphyry, quartz porphyry, aplite, pegmatite, diabase and lamprophyre—probably differentiates of the granite. The granite and associated rocks may have been the source of the gold. The deposits are clearly pre-Keweenaw in age. Lying on the granite and greenstones are a few remnants of Animikie sediments (Cobalt series). These sediments and all the older formations have been intruded by numerous narrow dikes and sills of Keweenaw diabase. The silver deposits are Keweenaw or post-Keweenaw in age.

## Gold

**McKellar-Longworth (B. J. 122)**—Four veins carrying visible gold have been located on this property in a large east-west fault zone which has been traced for over 2 miles. The westerly quartz vein is narrow, averaging 8 inches in width; however, it contains a considerable amount of gold and tellurides with some cobaltiferous mispickel, copper and iron pyrites. The vein has been exposed for a depth of 75 feet on a vertical cliff from which 20 tons of high-grade ore have been collected for shipment to a refinery. Farther east on the shear zone a 40-foot shaft has been sunk on a

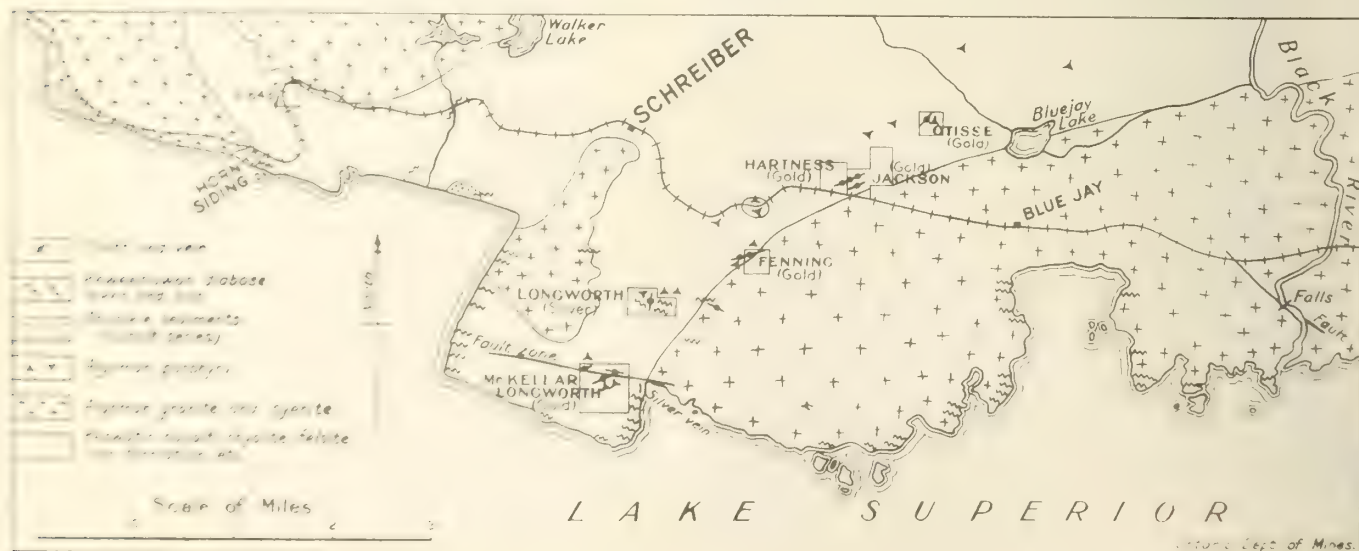

series of parallel auriferous quartz veins, one wall being quartz porphyry. Still farther east a 100-foot tunnel has been driven on a vein from one to five feet in width, the wider portions comprising quartz and schist. The quartz in places averages \$40.00 in gold per ton over a width of 1½ feet.

Messrs. Glendinning and Foster, who have the property under option, are taking out a car of high-grade ore which will be shipped to the Temiskaming Testing Laboratories at Cobalt at the end of this month.

**The Fenning Developing Co.** owns a group of 12 claims about one mile northeast of the McKellar-Longworth. In November, 1922, camps were built and mining commenced on Claim T. B. 3870. A shaft has been sunk 40 feet on a vein lying between a mineralized quartz porphyry and a dark hornblende syenite. The vein is highly fractured and contains a large percentage of chalcopyrite and small quantities of molybdenite, galena and telluride in a quartz gangue. No visible gold was seen but the manager stated that favorable assays in both gold and silver were being obtained.

**The Hartness Claim, T. B. 3354**, is situated on the railway 3 miles east of Schreiber. A few pits have been sunk on narrow parallel lenticular quartz veins, two of which carry high gold contents in places. One ton of ore from a vein 1½ feet wide yielded \$115.90 gold and 3.21 ounces silver. These veins extend easterly unto the **Jackson Gold Mining Co's.** claim, T. B. 3326. During the past year \$20,000. was spent on this property on buildings and prospecting. Two tunnels, 500 feet apart, have been extended into the hill for 50 and 100 feet respectively, exposing two parallel veins on which a few feet of drifting was done. A shaft has also been sunk 15 feet on a gold deposit of the stock-work type, the rock being a comparatively fresh diabase, probably of Algonian age. The diabase for one inch on either side of the veinlets has been metasomatically replaced by carbonate, quartz and pyrite. The **Otisse** claim No. 3412 belongs to the Jackson Mines. Gold is also found in Keewatin rock near the same granite mass 13 miles

\*Volume XXX, Part IV, 1921.

Schreiber Gold and Silver Area, District of Algoma, Ont.

Shaft and Tunnel Workings on the Jackson Gold Mining Co's Property, Schreiber, Ont.

east of Schreiber near Jackfish bay on the *Empress*, *Ursa Major* and other properties.

### Silver

As high as 10 ounces of silver per ton has been obtained from some of the gold veins already described. An important discovery of native silver was made  $1\frac{1}{2}$  miles south of Schreiber in September 1922, on the *Longworth Claim*, T. B. 3850, a re-staked portion of R. 684. The silver occurs in calcite, galena and quartz veinlets in a brecciated zone 2 to 3 feet wide with two well-defined vertical fault walls striking  $20^\circ$  E. of N. An open pit 24 feet long, 15 feet deep and 5 feet wide has exposed two small lenses of 100-ounce silver ore 3 feet long, 5 inches wide and 2 feet deep. The largest

piece of leaf silver was about  $\frac{1}{2}$  inch in diameter. Iron and copper pyrite, chalcocite and probably argentite are also present. The enclosing rock is an altered diabase which has lamprophyre and aplite phases. Time was not taken to determine whether the diabase was a sill or a dike. Under thin section the rock shows intergrowths of quartz and feldspar.

On the shore of Lake Superior one mile south of the Longworth silver vein and in the strike of it is a highly altered Keewatin rhyolite carrying galena and a little silver.

Some small quartz and calcite veinlets carrying galena and zinc blende occur in the Keewatin and the Animikie sediments near Horn Siding, 5 miles west of Schreiber. Two ounces of silver per ton was obtained from a small barite vein carrying fluorite, specular hematite and chalcopyrite at a 90-foot falls on the Black river, 7 miles east of Schreiber.

Argentiferous galens occurs on the C. P. R. 30 miles east of Schreiber on Claims C. 48. The vein is on the west bank of Dead Horse creek and 300 yards north of the railway. An east-west 2-inch vein of galens with some calcite, zinc blende and chalcopyrite has been exposed for 50 feet in diabase. One sample of galena assayed 42.5 ounces silver per ton.

In 1875, Peter McKellar of Fort William worked silver-bearing veins 5 miles to the north west of Middleton station on locations V.49 and V.40 on McKellar creek.

Although no commercial silver deposits have been found as yet in the vicinity of Schreiber, nevertheless there are numerous fractures carrying calcite, galena and other minerals which are worthy of being explored, particularly in the vicinity of Keweenaw diabase dikes or sills. The Silver Islet mine near Port Arthur produced \$3,250,000.00 in silver from the portion of a vein that lay within a diabase dike 300 feet in thickness.

### NEW J.-M. ASBESTOS PLANT

The Canadian Johns-Manville Co., has decided to proceed with the construction of its new manufacturing plant immediately weather conditions permit in the spring. It is still undecided as to where it will be located, and it is therefore not at all certain that it will be near the quarries at Asbestos, Quebec. The first building will be 500 feet by 1000 feet in plan, of concrete and steel and of single-storey daylight construction. The contract for the structural steel work has already been placed with the Dominion Bridge Co. of Montreal.

McKellar Longworth Claim.—Tunnel on East Vein: The quartz in the righthand side is 18 inches wide and carries visible gold.

# Placers at Dease Lake, B.C.

PROMISING GOLD PLACERS NOW BEING  
OPENED UP

By ROBERT DUNN

The Dease Lake country, some two or three hundred miles southeast of Atlin and seventy-five miles or more east of the trading centre at Telegraph Creek, in the northwestern corner of British Columbia, is the greatest placer mining district of British Columbia, according to George Adams, who is engaged there in hydraulic operations.

Mr. Adams is not one whose word should be taken lightly when it comes to placer mining. It has been his business for many years. For fifteen years he was the manager of the McKee Creek Hydraulic Co., Atlin, and prior to that roamed the hills of the north country, a prospector.

On Thibert Creek, one of the waterways draining into Dease Lake, Mr. Adams and associates have taken up a number of placer leases. With the leases they got a hydraulic plant, monitors, flume, tools, cabins, etc., etc. These were taken in or constructed by the late Warburton Pike, the celebrated western big game hunter and miner, and a company of British Columbians. They found gold but their plans had not ripened when war broke out. The call to arms was not to be denied. Tools were dropped, the water turned off, a clean-up worth some thousands of dollars neglected, and the entire camp made for the Coast. There they scattered, all to find their way to the fighting front, whence few returned.

Four years later Mr. Adams "took on" the enterprise. Things were in bad shape. Machinery had rusted and the flume had slipped in different places. He and his men got the camp shaped up, however, in a few months. The forgotten "clean-up" of 1914 was carried on and a few thousand dollars recovered and another pit was opened and some fourteen thousand dollars obtained.

With this evidence of values Mr. Adams decided to open up his ground in a broad way, to sink prospect holes at different points, to repair and enlarge the flume in order that a constant and adequate supply of water might always be available, and generally to lay the foundations for a really big hydraulic mining proposition. This is the work he has been doing for three seasons. His prospecting, he states, has established beyond question that the pay ground persists throughout the several miles of placer he holds under lease. Over a considerable section—if I remember right he mentioned 1,000 feet—it is as rich as it was in the first small pit he cleaned-up two or three years ago.

Two difficulties are being met with, one being the matter of transportation and the other having to do with water. As to the former, no trouble is experienced in getting machinery and general supplies as far as Telegraph Creek. From that point there is a good road for 22 miles to Toya River, but from Toya to the head of Dease Lake, some 50 miles, the route is marked by a trail. Of course, it is fairly open country and the trail, as trails go, is a good one; but Mr. Adams has big things in mind. He wants to take in much machinery to handle his proposition satisfactorily and economically. He therefore is asking the Provincial Department of Mines to assist in the opening up of a

road into the Lake and has been assured that, if his plans are matured as outlined, this will be done.

With regard to water, it is not that there isn't water but that it has been found hard to convey. The old flume has been a constant source of trouble. The bank upon which it is placed is given to sliding and this tendency has frequently interfered with operations. Mr. Adams will take in new plant and will undertake new construction that will remove this handicap and put him in a position to turn seriously to the work of making a few good "clean-ups". As stated at the outset he thinks the Dease Lake country holds mining possibilities very little appreciated by the outside world and that, with a good road, it will not be long before many enterprises similar to his will be successfully launched.

When Mr. Adams talks of the Canadian Northwest, or that part of it in from Telegraph Creek, he waxes enthusiastic not only as to its mineral riches but also in regard to its big game attractions. In the open seasons he and his men live largely on the flesh of moose, bear, caribou, mountain goats and sheep. The country abounds with such game. The moose and caribou are found in herds, the valleys, rich in their wild verdure, affording as pleasant ranges as are to be found anywhere on the American continent. Of the smaller feathered game, also, there is plenty. The "fool hen" Mr. Adams mentions specially. If a covey is treed in the evening on the trail a man may return with his gun at his convenience the next morning and count upon these toothsome birds, of little sense, being found awaiting his pleasure. Thus there is no sport in killing them, but they make a real delicacy for a table surrounded by a body of hungry miners.

The grizzly bear, the King of all Canadian Big Game, also makes his home in the Dease Lake territory. Mr. Adams is a woodsman and a hunter as well as a miner. This, probably, accounts for the wholesome respect with which he refers to the "grizzly." Here is a story, told by him in much the same words he used, which struck me as being much to the point.

"We had some moose meat cached where it had been killed a few months before, about fifteen miles from camp. It was winter and so the meat had frozen and kept its freshness. I and an Indian started out with dog team and sleigh one morning to bring in the meat, intending to lunch at the cache where we had some tea and other supplies. The carcasses had been placed on poles suspended between two trees some eight or nine feet from the ground,—at any rate so high as to be considered safely out of reach of anything that might wander through the forest.

"On reaching the cache the meat was seen to be disturbed. A quantity was lying under the poles. There were tracks in the snow as large in circumference as the average wash basket and the snow was so crushed that it was clear that Bruin had been lying down after enjoying his stolen meal.

"Pete, we're going to load what's left and hike a few miles before eating."

"Aw, what's the matter?" exclaimed the half-breed. "We've got a gun."

"Right you are," said Adams, "but who's going to use it if the bear comes back?"

"I will, if you're afraid," taunted the Indian. "Besides, he's running. Look!" and he pointed to the packs, "the dogs frightened him. He went at a gallop, and when they go that way there is no danger."

"All the same," said the cautious miner, "I didn't come here big-game hunting. I don't aim to enter into single combat with the Goliath of the Grizzly tribe, armed with one medium-weight rifle. So let's wait at it."

And beat it they did.

### THOMAS J. BROWN

Mr. T. J. Brown, who succeeds Mr. Hiram Donkin in the position of Deputy Minister of Mines for Nova Scotia, entered upon his duties during the month of January. Probably no more popular selection could be made either from the standpoint of the province, the coal companies or the miners of Nova Scotia. Mr. Brown is a man of long and varied mining experience, his life having been devoted to the profession of mining, together with steel making, over a period of more than forty years.

He began work in a colliery office as a boy and there learned the business of operating a coal mine. From Inverness he was transferred to Victoria Mines office where he applied himself assiduously to the study of coal mining. After a few years of service he was appointed Manager of this colliery and retained the position until a depression of the coal trade shut down the colliery. He was then given charge of Caledonia (now Dominion No. 4) Colliery. From there he went to the General Office as assistant to Mr. Donkin, who was then General Manager. Being offered a position as General Superintendent at Trenton for the Nova Scotia Steel and Coal Company, he accepted. Here he began his experience in the manufacture of steel. On extending the Scotia steel plant to Sydney Mines, Mr. Brown went back to his old home town, North Sydney, as Resident Superintendent, having charge of both coal and steel operations. He held this position for fifteen years, but relinquished it when appointment was made by the Company of a man with whom Mr. Brown had nothing in common. It was only a short time until Mr. Brown was again in charge as General Superintendent, and there was general rejoicing among the employees.

Mr. Brown took an active interest in the mining legislation of the Province and was a member of a Commission on electricity in the coal mines, which made inquiry into the conditions of Nova Scotia collieries with a view to using electricity as motive power. The results of that work are now being realized and the less dangerous collieries of the Province are being gradually electrified.

Mr. Brown is a member of the Canadian Institute of Mining and Metallurgy, the Mining Society of Nova Scotia and the American Society of Civil Engineers.

One of nature's noblemen, he is the soul of honor and as an employer the "beau ideal" of the working men. With his name are associated all those attributes with which we clothe the employer who is considerate, humane, just and merciful. His is a big, kindly nature, which attracts men and makes friends of them.

The miners of Cape Breton hold Mr. Brown in the highest regard, and he would be a bold workman who even in the time of the acutest labor agitation would dare to utter one word publicly against T. J. Brown, as he is called by his workmen. How much the public of Nova Scotia owe to the tact, the resourcefulness, and the square dealing of Mr. Brown, they will never know. It is the appointment of just such men into executive positions that tends to make the Company or Government they represent popular and respected.

MR. T. J. BROWN

With an expert knowledge of coal mining, gained over a period of forty years, Mr. Brown will fill the position of Deputy Minister of Mines with ability and dignity, and no doubt with success. It goes without saying that the confidence of the miners of Nova Scotia will not only be retained by the Mines Department, but in addition will be further strengthened. Mr. Brown's appointment is cause for congratulation both to himself and to the Government that selected him.

JOHN MOFFATT.

Titanium is present almost universally both in igneous rocks and in the sedimentary rocks derived from them. Of 800 igneous rocks analysed by the U. S. Geological Survey, 784 contained titanium. It is estimated that the crust of the earth contains 0.44 per cent. titanium, or 0.73 per cent. titanium dioxide, this being the ninth element in the scale of abundance.

A serious attempt is being made by the United States Bureau of Mines to evolve a method for reducing the high silica content of the brown iron ore of Birmingham, Alabama, of which a huge tonnage is available.

## LETTERS FROM READERS

To the Editor,

Canadian Mining Journal.

Sir:

I should very soon have assumed responsibility for some little controversies with Professor Haultain. Unfortunately I could not believe that he could or would take seriously a paragraph that was patently playful.

Since Professor Haultain has made a heavy issue of my innocent persiflage, I wish to assume the burden of guilt myself and to express my regret that his feelings were irritated with

The comforting fact is that no one but Professor Haultain could take the matter seriously.

Kingston, Ont.

J. C. Murray

*A Western View of Institute Affairs*

To the Editor,

Canadian Mining Journal.

Sir:

May I venture to make some criticism of your two Editorials in which you refer to the affairs of the Institute in your issues of January 12th. and January 19th. last.

In the first of these comments, under the caption "A Danger Signal," you express the view that the acceptance of gifts of money from corporations is fraught with very grave danger to the Institute. Contrasting this attitude with that which prevailed at the Council meeting held in Vancouver in November last, at which I was present and at which this subject was introduced and discussed under the chairmanship of our President, one does not receive a favorable impression of view-point. It seems in fact, rather jaundiced; and I think it may be conceded that the Institute is above the pretty imputation of being prejudiced by acceptance of tributes that's worth

But, getting down to facts, — such phrases as being "bound hand and foot by fetters" of course sound very alarming, but just what does this mean in this case? What is it that is so threatening to an Institute that has nothing to do with serving any class? In the words of the ancient Jews, "We cannot tell what it is", — and I hardly think that anyone else does either. For even though the motive behind the gift were venal, the Institute's activities could be in no way hampered. For instance, if I were a doctor and a gentleman interested in the undertaking industry came to me and offered me a million dollars in appreciation of my work, I might think him a fool, but I should not feel called upon to impute to him the intention that I should expend the money upon the dissemination of poison germs, neither should I feel called upon to do so, nor to refuse his gift, — certainly not.

In regard to the second Editorial referred to, will you pardon me for saying that it is wrong to state that the proposed amendments to the by-laws, "would exclude all others" than those technically trained or qualified. I need do no more than quote from the amendments;— "Members shall have been in responsible positions with regard to mining or metallurgical work." If this does not clearly and definitely convey, as it was intended to do, the idea of responsibility as being the keynote and the essential requirement, I fear that no words of mine can do so; there is therefore no more to be said upon that score.

Let it be once understood that what we are all interested in is the promotion of the influence of the Institute; let it be understood that influence and responsibility go hand in hand, and I agree with you, Sir, that there is small danger of our Institute failing in its service to Industry. But let there be no mistake, — the conception of responsibility in members must be accepted and provided for, and that is the purpose of the amendments; and as a matter of fact, I do not believe there is already any very great difference of opinion about this.

Vancouver, B. C.

H. G. Nichols.

## NEW EXECUTIVE OF C. I. M. &amp; M.

The following have been nominated for office in the Canadian Institute of Mining and Metallurgy for the coming year, commencing March, 1923. As there has been only one nominee for each position, the election is uncontested.

**For President**

John A. Dresser, Consulting Geologist, Montreal, Que.

**For Vice-President**

Nova Scotia: C. M. Odell, Consulting Engineer, Sydney, N. S.  
Quebec: Thos. Denis, Superintendent of Mines, Bureau of Mines, Quebec, Que.

Ontario: R. L. Peck, Refinery Manager, British America Nickel Corporation, Ltd., Deschenes, Que.

Manitoba: R. C. Wallace, Professor of Geology, Manitoba University, Winnipeg, Man.

Alberta: J. A. Allan, Professor of Geology, University of Alberta, Edmonton, Alta.

British Columbia: Thos. Graham, General Superintendent, Canadian Collieries, (Dunsmuir), Ltd., Cumberland, B. C.

**For Councillors.**

Nova Scotia:

T. J. Brown, Sydney Mines, N. S.  
Geo. D. Macdougall, Trenton, N. S.  
F. W. Gray, Sydney, N. S.  
D. H. Macdougall, Sydney, N. S.  
F. H. Sexton, Halifax, N. S.

Quebec:

N. R. Fisher, Thetford Mines, Que.  
J. J. Penhale, Sherbrooke, Que.  
J. R. Pearson, Asbestos, Que.  
Geo. C. Riley, Dragon, Que.  
J. G. Ross, Montreal, Que.

Ontario:

John McLeish, Ottawa, Ont.  
G. C. Bateman, Cobalt, Ont.  
W. H. Collins, Ottawa, Ont.  
Geo. E. Silvester, Toronto, Ont.  
Geo. H. Gillespie, Madoc, Ont.

Manitoba and Saskatchewan:

T. R. Deacon, Winnipeg, Man.  
B. S. McKenzie, Winnipeg, Man.  
J. A. Campbell, The Pas, Man.  
J. P. Gordon, The Pas, Man.  
R. J. Lee, Estevan, Sask.

Alberta:

A. C. Dunn, Edmonton, Alta.  
John Shanks, Nordegg, Alta.  
J. A. Church, Edmonton, Alta.  
Geo. Kellock, Coleman, Alta.  
W. A. Davidson, Rosedale, Alta.

British Columbia:

M. E. Purcell, Rossland, B. C.  
H. N. Thomson, Vancouver, B. C.  
H. Mortimer-Lamb, Vancouver, B. C.  
Nicholas Thompson, Vancouver, B. C.  
Horace G. Nichols, Vancouver, B. C.  
Bernard Caulfield, Coal Creek, B. C.

The average daily production during 1922 of electric power in the United States for public utility stations was 130,600,000 kilowatt-hours. Of this 36.2 per cent was produced by water power. In Canada less than five per cent of the power from central stations is developed from fuel, the proportion for water power in 1920 being 97 per cent.

# Canadian Oil Shale

## REPORT ON BITUMINOUS SHALES IN NEW BRUNSWICK AND ELSEWHERE

The Geological Survey, Ottawa, has issued recently Memoir 129, *Geology of the Moncton Map-area*, by W. J. Wright. The report of 70 pages is accompanied by a topographical and a geological map of the area on a scale of a mile to the inch and two detail maps of the principal oil shale areas at Albert Mines and Rosevale.

### Geology

This part of New Brunswick has long been known as oil bearing. The "albertite" of Albert Mines was probably the finest fuel that was ever produced. Sporadic attempts have been made to utilize the promising oil shales of the district, and a serious attempt has lately been in progress. The area is highly productive of natural gas. Beds of gypsum give promise of substantial production, and there are some interesting deposits of rock salt.

Dr. Wright's study has been essentially geological, as the Carboniferous rocks of the area have presented numerous unsolved problems. Some of these he has solved, and others remain for future investigations. The oldest rocks of the map-area are pre-Carboniferous possibly as young as Devonian, consisting of much folded and altered igneous and volcanic rocks. At the base of the Carboniferous series, laid down on the eroded surface beneath, is the bituminous Albert series, which contains the beds of rich oil-shale and is the source of the gas and oil in Albert country. This series is 5,000 feet or more in thickness. Above it lie later series of an original thickness of 5000 to 8000 feet, which now provide a large part of the present rock exposures. One of the geological problems is the extent to which the oil-bearing Albert series underlies the folded and tilted rocks of these later series. It is in the Hillsborough series, near the top of the geological scale, that the gypsum beds occur.

### The Oil Shale at Albert Mines

"In Canada, the presence of rich oil-shale in the Maritime Provinces has been known for many years, and considerable money has been spent to determine its value, but no attempt has been made to develop it. The reason for this is apparent. The oil-shale industry is a big manufacturing proposition involving an initial outlay of millions of dollars, large supplies of oil-shale, and careful preliminary experiments by chemical engineers, and the chief product must compete with oil obtained by established companies from flowing wells. At best, the returns are only a reasonable amount on the sums invested. But the oil situation demands new sources of supply. Already reliable companies are looking over the situation and some preliminary experiments have been made. It is hoped that operations will be started shortly, and that the experience and confidence gained from a successful industry in the Maritime Provinces will lead to the establishment of similar industries in other parts of Canada."

Detailed evidence is given as to the quality and quantity of some of the beds of shale, diamond-drill cores as well as rock outcrops being used. The sum

of the evidence available in the Albert Mines area, 20 miles south of Moncton, is as follows:

"Several geologists of note have examined the oil-shale deposits of Albert Mines and estimated the amount of shale and the probable yield of crude oil and ammonium sulphate. The consensus of opinion is briefly as follows: in an area 4,000 to 6,000 feet long and 1,000 to 1,500 feet wide most of the rocks exposed are oil-shale. Furthermore, oil-shale makes the bulk of the rock fragments in the soil. In this area is the gash from which the albertite was removed to a depth of approximately 1,400 feet, and several shafts and tunnels. All of these workings are said to be in oil-shale, and this is supported by the predominance of oil-shale in the dumps from the main and east shafts. The conclusion is that this area is underlain almost entirely by oil-shale to a depth of 1,400 feet. Samples of shale from several points in this area yielded from 32 to 52 imperial gallons of crude oil and 38 to 92 pounds of ammonium sulphate per long ton. On this basis the average yield for the whole body of shale is estimated to be in the vicinity of 40 gallons of oil and 57 pounds of ammonium sulphate per ton. If these conclusions be correct there is here sufficient oil-shale to supply a large oil-shale industry for upwards of 100 years.

"The conclusions mentioned above were supported by the author in 1913, but modified in 1914. Since then it has been found: (1) That the above-mentioned area is underlain by shale which varies from rich oil-shale to barren shale, and some sandstone. The richer the shale, the better it withstands weathering. As a result oil-shale forms most of the outcrops and boulders, whereas the barren shale is not exposed, except in the places where the streams are rapidly removing the soil. (2) Erosion has opened about 791 feet of the measures of which about 50 per cent is exposed, and the remainder covered by soil. The richest known beds (about 3 per cent of the whole) have been analysed and found to be excellent oil-shale. (3) The workings of the albertite vein cut the shales where they are dipping at angles of about 75 degrees and penetrated only about 380 feet of measures. The fact that the shale extends to a depth of 1,400 feet in these workings does not prove the depth of the shale where the measures are lying almost flat, for example along Frederick brook below bed No. 1. In fact it is doubtful if the above workings reached bed No. 1."

The conclusion is, in effect, that there are indications of a very large tonnage of rich oil shale, but that to prove their extent and richness, much more exploration must be done.

### The Rosevale (Baltimore) Area

About the Rosevale, or Baltimore, area, 39 miles southwest of Moncton, there is very little information available. Outcrops show promising oil-bearing beds, but their extent has not been proved. Some diamond drilling has been done, but the results were not available to Dr. Wright. The D'Arcy Exploration Company, a subsidiary of the Anglo-Persian Oil Company, has experimental work under way in this area.

*Other Occurrences*

The concluding pages give a resume of the known occurrences of bituminous shale in Canada. In British Columbia, no workable deposits have yet been found. In the Pasquia hills of Manitoba, oil shale has been located, but analyses indicate a low yield of oil and ammonium sulphate. Bituminous shale is widespread throughout Ontario, but so far as known it is all of low grade. In Quebec, likewise there are large areas of Utton shale, containing small percentages of oil. In the Gaspé peninsula, however, there are beds of shale in the main unexplored, that warrant detailed examination. At numerous places outside the Mone-ton area rocks of the Albert series are reported as oil-bearing.

Nova Scotia has very promising beds of oil shale, particularly in Pictou county near New Glasgow. Mr. Harold C. E. Spence has under way a serious attempt to utilize the shale of this area.

**NEW DEPOSIT OF HIGH-POTASH FELDSPAR**

THE GILSON-CAMPBELL FELDSPAR QUARRY

By A. M. CAMPBELL

During the past four years, the writer has spent much time studying the feldspar situation generally and investigating occurrences of this mineral in Ontario and Quebec. Finally, in December, 1921, his efforts to locate a new deposit of outstanding magnitude and promise were rewarded when his attention was drawn to outcroppings of feldspar on the west half of lot number twenty in the ninth concession of the Township of Bathurst, Lanark County, Ontario. During that winter the top of the ridge was cleared of timber and underbrush, and subsequent work in the form of extensive stripping, test-pitting and other development has tended to prove that the initial sizing-up of the property was correct.

*Description of the Deposit*

This deposit consists of a huge dike of feldspar, 300 feet wide (as shown by openings and strippings), one thousand or so feet long, and with the main mass rising in a rounded knob or hill 40 to 60 feet above the level of the main highway that traverses the property. Regardless of what there may prove to be on the remainder of this one-hundred acre lot, there seems every reason to expect that this hill will eventually produce many hundreds of thousands of tons of a commercial grade of feldspar. For the present we are confining our operations to the eastern end of the ridge, and even that portion of the deposit could, doubtless, furnish enough crude 'spar of the quality required for the ceramic industry to satisfy the requirements of American importers for many years. In fact, an inspection of it has satisfied the representatives of several American grinding companies that at last a deposit of high-potash feldspar has been found of sufficient size and purity to provide a large and reliable source of supply of uniform quality.

The orebody forms part of a coarse-grained pegmatite intrusion that can be traced across this part of Bathurst township for a mile or two. In this portion of it, crystallization has taken place so as to separate large masses of feldspar. As usual, the dike does not consist wholly of good material, but includes segregations of

feldspar crystals. This coarse crystallization usually occurs in the larger dikes when they cut hard rocks, such as granites and gneisses, as this one does. The spar here is of the orthoclase variety and ranges in colour from white, through pink, to red. While we are at present mining pink and flesh-red 'spar, we recently uncovered, in a near-by portion of the dike a pure white potash 'spar similar to the highest grade ore coming from the Buckingham, Quebec, deposits.

*Quality*

Regarding impurities, I might say that there appears to be less quartz than usually occurs in such dikes. So far, no mica has been encountered in our workings, and the amount of other accessory impurities, such as tourmaline, pyroxene and iron pyrites, is, on the whole, negligible. In several places on the dike there is a graphic intergrowth of quartz, but its quantity per cent. is not sufficient to affect appreciably the quality of the 'spar. In our principal opening we encountered a zone of oxidation, with its accompanying discoloration, which extended for some distance in depth, but we have now gone below this, into clean 'spar.

The analysis of a representative sample of our ore, made at the laboratory of the Mines Branch, Department of Mines, Ottawa, gave the following results:—

|                              |        |
|------------------------------|--------|
| Silica . . . . .             | 65.10% |
| Ferric oxide . . . . .       | trace  |
| Ferrous oxide . . . . .      | 0.11   |
| Alumina . . . . .            | 21.50  |
| Lime . . . . .               | 0.11   |
| Magnesia . . . . .           | 0.06   |
| Oxide of potassium . . . . . | 12.81  |
| Oxide of sodium . . . . .    | 0.58   |
|                              | <hr/>  |
|                              | 100.27 |

A previous analysis gave Silica, 65.01 per cent., Alumina 19.82 per cent., Potash 12.61. per cent., etc., while others gave 11.66 per cent. and 12.89 per cent. of Potash.

*Transportation*

The 'spar is hauled by wagon or sleigh about five miles to the Canadian Pacific Railway station at Glen Tay (4 miles west of Perth, Ontario) over a comparatively level and good road which runs through the property. To connect the hill top working with the main highway, about 200 yards of new road had to be built.

While our operations have been somewhat delayed from various causes, a fair amount of ore has been shipped and the property is now equipped to provide for a larger production. Enough development has taken place to satisfy not only the owners, but also certain users that this deposit is capable of the consistent shipment of large amounts of merchantable feldspar annually. Large users of 'spar realize what it means to be certain of getting all the ore they require from a single quarry, thus securing a uniformity of grade not otherwise obtainable.

The new smelting plant of the Cerro de Pasco Copper Corporation in Peru, began to operate this month. For the past three years it has been under construction. Its capacity is 1500 tons a day of ore.

# Oil Engines for Mines

FAIRBANKS-MORSE "Y" TYPE FROM  
10 to 300 H. P.

The advantages of oil-driven engines for motive power and the production of electricity under certain circumstances in Canadian mining camps is becoming increasingly apparent. As the fuel has to be imported and in some cases transported for long distances, the oil engine is by no means the ideal source of power, but where no hydro-electric power is available, or where there must be auxiliary power as a stand-by or to supplement hydro-electric power, an oil engine installation is hard to beat. Of course, where coal is abundant and cheap, a steam plant is the logical solution of the power problem; but in areas like northern Ontario and Quebec, the oil engine is coming into use at a rapidly increasing rate.

Before an ore-deposit is proved, that is before it actually becomes a mine, circumstances seldom warrant the expense of a hydro-electric power development or a long transmission line; yet power is needed in considerable quantities to run the compressor, hoist and pumps. The

In practically all sections, however, the price of gasoline is much above that of other products of crude petroleum, and in many places this advance in price has been shared by kerosene, so there is a real need for engines that will operate on much lower grades of oil such as the heavy Solar oils, gas oils and fuel oils, or even the crude oils as they come from the wells. In each locality there will be some of these fuels that may be obtained at less cost than the others, and the ideal engine is the one that will handle all practical fuels without change and at the same time economically.

To meet this need of a reliable and economical oil engine, free from complications, a line of engines known as the "Y" type has been developed by Fairbanks-Morse and Company, ranging in sizes of 10 to 25 horse-power in the horizontal type and from 37 1-2 to 300 horse-power in the vertical type. They embody the results of years of experience with internal combustion engines of all kinds,

---

Fairbanks-Morse "Y" Horizontal Oil Engine.  
made in sizes 10 H. P. to 25 H. P.

---

wood fuel within reach is seldom adequate for more than the initial development, when a tiny steam hoist and a steam drill are used for the prospect shaft. The power problem is one of the most pressing considerations as soon as the property passes the stage of a mere prospect.

## *Adaptable to a Wide Range of Fuel Oils*

The internal combustion engine has come into such universal use during recent years that the technical public no longer requires special proof its economy and reliability.

Undoubtedly the greatest single step since internal combustion engines were first produced, was the use of liquid fuel directly in the cylinder of the engine. The results of that invention have been of world-wide importance. It made possible the development of all modern gasoline engines, such as are used in automobiles, trucks, airplanes, tractors, high-speed power boats, and in practically every other important industrial application.

The situation in the production, refining and cost of crude petroleum has been changing very rapidly in the last few years. Conditions even now are not the same in any two large commercial centres, so the question as to which of the various liquid fuels is best is still a local one.

coupled with careful study and investigation of oils and oil engines at home and abroad, together with extensive experimental work covering long periods. They are adapted to any stationary power purpose within their range of capacity. They can be belted to line shafts to drive mining machinery, etc., or may be belted direct to an air compressor, pumps, electric generator, etc. For the generation of electric power these "Y" engines can also be direct connected to a generator. In any case they are equipped with fly-wheel of sufficient weight to prevent pulsations or flicker in the electric lights from the generators, and they may be arranged for parallel operation of two or more similar units on the switchboard. The company are prepared to guarantee successful parallel operation with 60-cycle alternating current generators direct-connected to any of the vertical "Y" Engines of one or more cylinders. This indicates the closeness of governor and flywheel regulation attained with these engines, as it is well known that there is no more exacting service than that just referred to.

These engines have also been used successfully at mines for hoisting. This is an exacting requirement, and demonstrates the degree of reliability to which the present-day oil engine has attained.

*General Principle of Operation*

The "Y" engine operates on the two stroke, moderate pressure principle, with the fuel injected into the combustion chamber by means of a simple pump, properly timed, and controlled by the governor in proportion to the load on the engine. It is not a hot bulb engine, as the combustion

50 H. P. "Y" Vertical Oil Engine for Belting to an Electric Generator

chamber is entirely water-jacketed. There are no hot plates or firing pins, but the heat remaining in the combustion chamber, together with that produced by the compression of the charge of air, ignites the oil, which burns with more of an expansive pressure than the explosion of the ordinary internal combustion engine. This system of combustion is a development accomplished only by painstaking work on a great variety of designs, each of which was completely tested and tried out in many modifications, and represents the highest development in simplicity, economical operation and reliability obtained in oil engines to date.

*Features of "Y" Engines*

As they use the solid injection principle, these engines do not require two or three-stage high-pressure air compressors, which are always an expensive auxiliary to maintain, and which absorb from 10 per cent to 15 per cent of the total power generated.

There is an absence of all inlet and exhaust valves, which reduces the care in maintenance and the expensive renewals of such parts.

Owing to the lower working pressure and temperature of the "Y," it costs materially less for the maintenance of its mechanical parts, which are few in number and of rugged simplicity in design.

Coupled with these points of economy in its mechanical features, the simplicity of the "Y" engine makes a highly skilled engineer unnecessary. An attendant with a short experience in operation machinery, after a brief course of observation and instruction by the installing engineer, can operate it with entire success.

References to the test records and the guarantees on fuel consumption show the advantages of the "Y" engine in economy of fuel.

*Fuel Oil Specifications*

As indicated above "Y" engines operate with satisfaction on the lower grades of oil, such as the heavy Solar oils, gas oils and fuel oils, or even crude oils as they come from the wells. From the very nature of petroleum, whether in the crude or partially refined condition, its composition is very complex, and fuel oils really consist of mechanical mixtures of a great variety of distillates and residues, in proportions that are scarcely twice the same. Many scientific attempts have been made to prepare specifications under which oils might be purchased so as to eliminate all that might be unsatisfactory for engine use and yet exclude none that could possibly be used. So far these attempts have not been truly successful, and the final test of the value of a fuel oil is its operation in an engine. The amount and nature of the residual content in an oil is not a measure of its value as an engine fuel, as it must always be considered in relation to the proportion of lighter or more volatile components that will help to "carry" or thin the heavier portions.

Generally speaking, fuel oils offered by responsible oil companies under certain brands or descriptions are reasonably uniform, and a complete examination of a suf-

20 H. P. "Y" Furnishing Light for a Lead and Zinc Mine. Note also the 150 H. P. "Y" Vertical Engine in the background

Performance Tests

ficiently large sample of the oil in question will indicate whether or not it would be an economical fuel. The manufacturers of this engine have made complete physical, chemical and distillation tests of oils for many years, and the results of these tests are at the disposal of their customers. They also stand ready to assist operators of "Y" engines at any time by making complete examinations and reports on fuel oils that may be offered for their consideration, without charge.

This appears to be a much more rational way of coping with the constant changes in the character of fuel oil than an attempt to regulate the supply of oil by means of specifications. Time and trial have shown that this is the better way.

#### Tests And Guaranties

Each "Y" engine at the factory is given a thorough test at partial load, full load and over-load, and the results

are recorded for future reference. The object of this test is to ascertain that the engine is in perfect mechanical working order, or to correct any points that need it, and to make sure that it operates well within the standard guaranty of fuel consumption. In this particular it is preferable to maintain a conservative policy, and not to rate the engines either in their horsepower output or in their fuel consumption dangerously near to the best they can do. The margin allowed on these points is for the greater satisfaction of the users and insures against disappointment.

The standard guaranty is that the "Y" engine will develop its full rated brake horsepower at sea level on a consumption of 0.60 pounds of approved fuel oil per brake load. By "approval fuel oil" is meant one that is included in the maker's list of such fuels or that may be approved after being tested. The relation between the fuel consumption guaranty, as just stated, and actual results from the regular factory tests is shown by the curves on the accompanying cut. It will be noted that the actual fuel consumption of the engine is much less than the guaranty.

#### Fuel Cost

The fuel recommended for type "Y" engine in Canada is easily obtainable from the several leading Canadian oil companies. This fuel has a gravity test of 31 deg. to 35 deg. Baumé, weighing between 8.67 and 8.47 lbs. per imperial gallon. Translating the figures on the chart from pounds to liquid measure, the fuel consumption would be 0.085 imperial gallons per brake horsepower hour at full load, 0.092 imperial gallons at three-quarter load and 0.099 imperial gallons at half load. Taking the laid-down cost of the fuel at 15 cents per gallon the fuel operating cost would be approximately one and one-quarter cents per brake horsepower hour at full load.

### THE EMPIRE'S GOLD PRODUCTION

The following table, prepared by Mr. Joseph Kitchen and published by Samuel Montagu & Co., London, indicates the place of the British Empire and of Canada in the world's production of gold. Mr. Kitchen says: "Canada is the only country to show a marked improvement [in gold production] and it now ranks as second producer in the British Empire and third in the world."

"1922 will probably have seen the end of the decline in total output that has been proceeding since 1915, the year of high-water mark, and 1923 is likely to show a notable improvement, which may reach £10,000,000 or £11,000,000. This will be mainly due to the Transvaal, which for the last six months of 1922 produced £19,400,000 as compared with £17,700,000 for the corresponding period of 1921."

|                             | 1922 est.          | 1921               | 1920               | 1919               |
|-----------------------------|--------------------|--------------------|--------------------|--------------------|

## MINERAL RESOURCES OF VANCOUVER ISLAND

The following memorandum on the known mineral resources of Vancouver Island and vicinity was presented to Sir Henry Thornton, president of the Canadian National Railways, on his visit to Victoria recently, and is reprinted from the "Daily Colonist":

Vancouver Island, with an area of 16,000 square miles, has coal measures covering some 2,000 square miles. It occupies an exceptional position in this connection, as it possesses the only high grade bituminous coalfields north of Peru, thereby controlling some 5,000 miles of the Pacific coast, with the exception of the State of Washington, where the coal is of low grade, being a semi-lignite.

Official tests of the United States Navy show that it takes 112 tons of Vancouver Island coal or 145 tons of Washington coal to produce the same heat unit as 100 tons of the highest grade Welsh or Pocahontas steam coal.

Only such seams as it has been necessary to develop to take care of the present market have as yet been opened, but there is enough coal blocked out to provide for the present rate of requirements for the next 50 to 100 years. Vancouver Island produces 75 per cent of the coal tonnage of British Columbia. The output of the Island mines varies from 1,500,000 to 2,000,000 tons annually. The present cost at the mines averages \$6.75 per ton. If the market could be developed to the point of enabling the mines to operate at capacity, it would materially reduce the price by reason of the reduction in overhead and furnish additional employment that would add many thousands to our population.

### Iron Ore

Vancouver Island occupies the same advantageous position in relation to the North Pacific coast on iron ore deposits as it does on coal. It is a fact that there are no good iron ores on the Pacific coast south of British Columbia.

The commercial iron ore bodies of Vancouver Island probably approach in size that of all the other iron ore resources in British Columbia which are near enough to the coast to be of immediate importance—(Whittier).

The best known sources of iron ore are on Texada Island, immediately adjacent to Vancouver Island. The United States battleship Nebraska, constructed at Seattle, was partly manufactured from Irondale Pig, made from Texada Island ore.

Hayes estimates the iron ore deposits of Texada Island of commercial grade as approximately thirty million tons. Wilmott estimates that on the Godman properties at Gordon River, there are available fifteen million tons, including the ore on the Bentley group.

Brewer estimates the deposits at Upper Quinsam Lake of magnetite ore as five million tons.

The Western Steel Corporation's holdings of bog ore situated at Quatsino Sound, contain approximately ten million tons. There are large deposits which have not been measured on Buggaboo Creek, the Sooke District, at Sarita River, and along the Alberni Canal, Nootka Sound, Klaaneh River, Klinak Lina River and Upper Campbell Lake, many of which give indications of still greater volume than those mentioned as having been more accurately measured.

There was produced in the Victoria district last year over one million dollars in miscellaneous non-metal-

liferous deposits, including lime and limestone, tale pottery clay, firebrick, cement, etc.

### Gold and Copper

The Island is rich in metalliferous deposits. Gold is found in the black sands at different points and the sand and gravel of the Leech and other rivers is gold-bearing.

The gold and copper deposits of Vancouver Island are varied in extent and indicate large future development. The Sunloch Mines, situated at Jordan River, 45 miles from Victoria, consisting of some thirty claims, have been purchased by the Consolidated Mining Company, of Trail. The property is situated close to tide-water and the company purposes, and has in view, the erection of a large concentrating plant at that point. The copper-bearing rock is not in vein formation, but the entire claims are copper-bearing throughout their length and breadth, averaging for the entire property two per cent copper, representing an enormous quarrying proposition offering probably the most economical cost of production in the Province. This property has been reported upon by eminent mining engineers as one of the largest copper deposits in Canada, the permanent nature of which has, we think, been proved by development work.

### To Build New Smelter

The same company owns the Coast Copper Company's property at Quatsino, where the ore-bodies are of sufficiently high grade and have been proved to an extent that has warranted the decision to erect a concentrator at that point in the early future. The report of the Government Minister of Mines for 1921 states that it is the intention of this company to build a copper smelting plant on the Island as soon as costs of construction and development work at their mines reach a satisfactory point.

The Tidewater Copper Company owns a valuable property at Sidney Inlet, the ore running from \$15.00 to \$20.00 per ton in gold and copper values. The mine operates a concentrator with a capacity of 200 tons per day, and sufficient ore is already blocked out to keep the mill running for many years. It has several thousand feet of underground workings and over 10,000 feet of diamond drilling, which has proved the depth and value of the vein.

Much more may be said, but we hope that the foregoing will convey to you in some small measure the immense possibilities that are lying dormant immediately adjacent to this port, which is Canada's gateway to the Pacific.

We ask you to consider these data in conjunction with the review made by Mr. Cameron on our timber and lumber resources, and we would add in addition that we have an almost unlimited supply of water power available for development. All these resources are immediately contiguous to one another. They form a set of factors which are bound to lead to a vast manufacturing development on this Island at a cost which should enable it to enter into world competition for foreign markets.

### Vancouver Island an Industrial Centre of the Future

The large manufacturing centres of England have to seek their outlet for foreign trade through the ports of London and Liverpool at a cost to seaport of \$3.00 to \$4.00 per ton.

Pittsburg has to seek its outlet via New York at a cost of \$4.00 to \$7.00 per ton, and the same thing per-

tains to the manufacturing cities of Germany. We have no such handicap, being situated immediately on the ocean.

The big commercial development of the future undoubtedly lies in the Orient. With sparsely inhabited Australia, the teeming millions of China, India, Siberia, and other countries, groping towards an Occidental civilization with all it implies in its vast consumption of manufactured material there is no country in the world so favorably situated in shipping transportation to these great potential markets as Vancouver Island.

Surely this wonderful combination of factors, the gift of Nature, and our geographical situation, form a combination which should result in a future development almost beyond our present power to comprehend.

The Canadian National Railway can, by its activities, assist in a great measure towards this end, and by so doing reap the major share of the benefits to accrue therefrom from a transportation point of view.

## Book Reviews

**THE RESCUE MAN'S MANUAL** — compiled by Arthur B. Clifford, M.S.M. — The Colliery Guardian Co., 30 Fumival Street, Holborn, London E. C. 4., England. — 46 pages — 1 shilling; by post 1s. 2d.

This little book is a convenient guide for those engaged in rescue work at collieries. It is couched in single language and is intended to supplement the work of a skilled instructor. It deals specially with conditions in Great Britain, but is applicable wherever breathing appliances are employed. It gives brief descriptions of all the appliances so far approved by the British Mines Department. Its low price puts the manual within reach of every man interested in mine rescue work.

**A PROGRESSIVE COURSE OF COMPARATIVE GEOGRAPHY** — By P. H. L'Estrange. — (new edition, revised and enlarged, 1922) — George Philip & Son, 32 Fleet Street, London E. C. M., and Renouf Publishing Co., 25 McGill College Ave., Montreal. — 168 pages and 75 maps. Fully illustrated — Price \$5.00.

The modern study of geography is not what it used to be — it is now rational, interesting and instructive. Since the good old days of twenty or thirty years ago a reform has been instituted, and one of the principal reformers is Mr. L'Estrange. No longer can the pupil memorize a list and then lead the class. He must now use all his faculties. Most remarkable of all, the study of nature, which comprises the bulk of the physical features of this globe, and of human nature, which has accounted for the rest, are now conceded their true value in primary and secondary education. Particularly striking is the concession that the elements of geology, without which no one can understand this world of ours, and a general estimate of our mineral industries, upon which civilization is built, are proper subjects of study for the children of the British lands.

This is a most admirable book, and should be in many Canadian homes, for the instruction of parents more than for the children. It is devised, of course, for school-room use, and is specially suited for that purpose. But for a general, well-balanced and suggestive survey of our globe, it will be hard to beat.

Mr. L'Estrange's firm grasp of his subject is well illustrated by some sentences in his preface. "Learners

must be induced to reason not to memorize, ... 'Human Geography' treats of the influence of environment on man's progress and of human ingenuity on environment, and is the only geography worth teaching as education ... An intelligent research into the past will enable us to understand the present and know how to work for the future ... No one can fully know how to live unless he understands the region in which he lives and the previous efforts of man to live in that region. ... The learner, starting with well-known everyday phenomena around him, is led to deduce from these some guiding principle, in accordance with the theories of the best physical geographers ... If it is known where a country is on the globe and how its mountains and plains are arranged, its temperature at various seasons, its winds and rainfall can usually be deduced. From these follow its natural vegetation and products, and the pursuit of its human inhabitants and their distribution."

With this we must leave Mr. L'Estrange to develop his subject in a book that has already marked an epoch in the study of geography.

### SILVER PRODUCTION IN 1922

In commenting on the world's silver production in their Annual Bullion Letter for 1922, Samuel Montagu & Co., London, remark that "Canada is producing nearly half as much again as last year, and encouraging reports are received as to the discovery of new mine fields." Their estimate of the 1922 production of silver is as follows:

|                        |            |
|------------------------|------------|
| Mexico .. . . .        | 75,000,000 |
| U. S. A. .. . . .      | 60,000,000 |
| Canada .. . . .        | 17,000,000 |
| Burma .. . . .         | 5,000,000  |
| Rest of World .. . . . | 30,000,000 |

Total .. . . . 187,000,000

E. Cecil Short & Co., of Montreal, Canadian agents for Wm. Benson & Son, Ltd., Newcastle-on-Tyne, have for distribution a catalogue describing "Benson" firebricks.

The Hardinge Company, New York, have issued a new catalogue (No. 13, January, 1923), which gives a general description of their conical ball and pebble mills and their use, and details about the standard sizes and varieties. The crushing action of the mill is clearly set forth, and facts are cited to show that the natural classification of balls or pebbles in the mill according to their sizes actually takes place, this contention having been controverted by the proponents of cylindrical mills.

There has been incorporated recently a new company, Webster-Inglis Limited, for the manufacture in Canada of the conveying, elevating and power transmission machinery of the well-known Webster Manufacturing Co. of Tiffin, Ohio, and Chicago. The new company is a subsidiary of the John Inglis Company, Toronto, and will make use of the Inglis shops. Mr. Wm. Inglis is President, and Mr. A. T. Perkins, Vice-president. Mr. Perkins is President of the Webster Company.

Of thirty-nine producing gold companies on the Rand, only three failed to show increased returns during the month of October last.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**POWER FOR HOLLINGER.** Confirmation of the acquisition of power rights on the Abitibi River by the Hollinger is reported to have come from the Government officials in Toronto. Details have not been given out, as it is understood that some of the terms have not been finally decided upon. Negotiations have been under way for some time, but there were a large number of points to be taken into consideration, particularly as the Abitibi Lake, from which the river flows to James Bay, is partly the province of Quebec. The Abitibi Paper and Power Company had also to be satisfied, and on account of its extensive development of the River it claimed to have prior rights. The site for the power development is stated to be at Island Falls, which is about 75 miles in a direct line from the Hollinger Mine. Officials of the Hollinger have previously stated that no action regarding dividends would be taken until the power question was settled, and if a lease has actually been obtained, it is now anticipated that some action on dividends will be taken at the annual meeting in March. The appeal of the Hollinger in respect to the \$2,000,000 suit against the Northern Canada Power Company was heard this week, but judgment was reserved. It is also understood that the Power company will bring a suit against the Hollinger to have the company sign for its entire power requirements. If the Power company is successful in this suit, it will prevent the Hollinger from developing its own power. Officials of the company, however, appear to be confident enough to go ahead with the proposals. It is understood that a new company will be formed to finance the power scheme, and that money will be raised by the sale of bonds to the Hollinger shareholders.

**GREAT NORTHERN POWER.**— Approximately five hundred men are at work on the power plant and transmission line of the Great Northern Power Company, which will endeavor to have power into the Porcupine camp some time this coming spring. The concrete work at the power house is practically completed, and the machinery for the first unit of 2150 h.p. is being installed. Fifteen miles of the transmission line to Porcupine has already been cleared, and camps are being constructed along the route so that work can be carried on from a number of points.

**PORCUPINE.**— The Porcupine Crown property in Porcupine has been closed, and it is understood that no further work will be done until some definite arrangements are arrived at regarding the dissolution of the North Crown Mine. The Thompson Krist has not been able to raise enough money to pay off its share of North Crown expenditures, and redeem its property, and it is understood that this will have to be done before the Porcupine Crown can resume.

The Coniagas has completed the unwatering of the Newray mine, which it has under option, and is now making an examination of the underground workings.

**KIRKLAND.**— At a recent meeting of the Kirkland Lake Proprietary, held in London, the chairman announced the sale of the company's interest in the Sylvanite property. He also stated that it had been found advisable to close down the mill as on account of the

small amount of development work, there was not sufficient ore in sight. The company proposes, however, to supply additional money up to a total of \$250,000, which is considered to be more than sufficient to place the company on a dividend paying basis. The terms of the deal for the Sylvanite were not announced, but it is understood that the figure is approximately \$600,000, which is to be paid within two months. The chairman stated that the company was to receive more than sufficient to pay off the indebtedness, which amounted to £120,000.

The shaft of the Sylvanite is down over 600 feet, and will be continued to a greater depth and a comprehensive scheme of development undertaken.

The Tech-Hughes shareholders have ratified the by-laws authorizing the company to purchase all the stock of the Orr Gold Mines. As about \$275,000 cash will be required, it is understood that the company will have to borrow some money to complete the deal. Substantial profits are, however, being made, and the company should soon be in a good position again shortly. It was also stated at the meeting that the company still had \$325,000 in bonds outstanding, and if these bonds are paid off before dividends are started, it will probably be some considerable time before any disbursements are made to shareholders.

The main shaft of the Wright-Hargreaves is down to 900 feet and will be continued to 1000 feet, where a new level will be opened up. In the veins hold their size and values at this depth it is anticipated that the mill will be enlarged some time during the present year.

**LARDER LAKE.**— During the past year the Crown Reserve made a little profit from sorting high-grade silver ore from the surface dumps at Cobalt. At the Pancake Lake Gold property the shaft is being sunk to the 500-foot level. On the 300-foot level two veins were drifted on for considerable distances, and each vein showed an ore-shoot 125 feet long, averaging about \$7.00 over a width of 15 feet. In order to finance further work on the Pancake Lake property, it will be necessary to increase the capital of the Crown Reserve.

**COBALT.**— During the month of January La Rose sank and timbered 155' 2" in the new Violet Shaft. This constitutes a new shaft-sinking record for Ontario, if not for Canada. The footage made is particularly good as during the first half of the month hoisting was done with a derrick using seven and one-half cubic foot buckets. The shaft is two-compartment and measures 11' 4" by 6' 4" outside the timber; but there was considerable over break. The rock is hard diabase but drills and breaks well. Three shifts of seven men each were used underground, but no the mucking shifts one man stayed on top to help the lander. A separate timber crew of four men does the timbering while the round is being drilled and the timber is kept within about 30 feet of the bottom. Four machines on bars were used and 18 to 22 holes were used to pull a round. An account of the short length of the shaft a 7½-foot cut hole was the deepest that could be drilled and a round averaged about 5' 9". The shaft was down 240 feet at the end of January and will probably be continued to a depth of over 600 feet.

## BRITISH COLUMBIA

**NEW CONCENTRATOR AT ANYOX.**—The Granby Consolidated Mining & Smelting Co., having practically completed a large capacity reservoir, thus assuring a constant and adequate water supply, is reported to be preparing for the construction at Anyox, B. C., of a large concentrator. A considerable quantity of the ore of the company's Anyox mines must be put through a mill and it is understood that other prospects are under development the ores of which will have to be similarly treated. The site of the additional plant will be on the railway between the mine and the smelter and it will be ready for use early next year.

**GRANBY AND CANADA COPPER.**—A report from Spokane Wn. has been received to the effect that the Granby Consolidated Mining Smelting & Power Co. contemplates increasing its capitalization from 250,000 to 500,000 shares, with a view to the purchase of the property of the Canada Copper Corporation, situated on Copper Mountain near Princeton B. C. It is said that the proposition will be voted on by stockholders at a meeting to be held at New York on February 8th. Unofficially it is affirmed that the Company has in view the expenditure of several million dollars but no definite information is given as to whether this is to be invested in betterments at Anyox and at the Cassidy Collieries, Vancouver Island, or whether the construction of a smelter near the Copper Mountain Mine is proposed.

The statement referred to, which is given on the authority of J. T. Crabbs, executive vice-president of the Granby Company, follows: "The Canada Copper is in process of re-organization. A new company is to be formed to acquire all of its properties and assets free of liabilities, and in addition it will have \$800,000 in the treasury.

"The properties are fully equipped. Engineers have estimated that they contain more than 10,000,000 tons of developed ore averaging 1.74 per cent. copper. A recent review of diamond drill and development records and an examination of the workings by our own engineers and geologist conservatively concede 5,635,980 tons of 1.83 per cent. ore, with values in gold and silver and probable increased tonnage as developments proceed.

"While the Canada Copper concentrating mill is up-to-date, additions will be necessary to insure a rated capacity of 2000 tons a day. The cash fund of \$800,000 is believed to be ample for the purpose and to supply sufficient working capital pending the receipt of income from operations. Satisfactory arrangements for transportation, power and treatment of concentrates have been made.

"Those entitled to a majority of the stock of the new company have signified to your directors their willingness to exchange such stock for Granby stock on a basis of 155,000 shares of Granby stock for 100 per cent. of the capital stock of the new company. The exchange is not contemplated unless 85 per cent. of the stock of the new company is acquired by Granby.

"Granby has 189,994 shares outstanding and the 60,006 shares remaining are required for the conversion of outstanding first mortgage bonds and debentures. The addition of 250,000 shares will leave 95,000 available for general purposes after acquisition of control in the Canada Copper. An issue for the 95,000 shares is not contemplated at present."

At the New York stock exchange valuation on Granby shares, which is upward of \$24 a share, Granby would pay \$3,750,000 for the Canada Copper.

**GRANBY WINS SUIT.**—The Privy Council has given judgment in favor of the Granby Consolidated Mining & Smelting Co. as against the Province of British Columbia, the amount at issue being \$63,000 which the Company claimed, should have been allowed under regulations allowing a discount of ten per cent. providing certain conditions are met in connection with payment. It was the contention of the Province that these conditions had not been complied with. This the Company combatted, asserting that the 1921 taxes were paid within the time limit set. In the Supreme Court the Company was successful but the Appeal Court of British Columbia upset the judgment of the lower court unanimously. The Privy Council, to which appeal was taken, not only upholds the lower judge but declares that all costs of litigation must be met by British Columbia. This is likely to add materially to the sum that must be provided by the Provincial Treasury in finally settling the dispute.

**RICH ORE FROM ROSSLAND.**—The I. X. L. Mine, situated on the outskirts of the Rossland mining camp, is reported to be yielding rich free-milling ore again. Some months ago mining men were startled by the richness of the mineral being taken from this property. A syndicate of Rossland miners had opened up a small but exceedingly high-grade stringer from which several shipments were made that brought them remarkable returns. It was assumed that the "pay" ran out as nothing has been heard of the I. X. L. for a period. Development, however, has been in progress and, judging from the latest advice, the enterprise of the operators is likely to be further rewarded. It is stated that the mine has paid the new owners some \$30,000, all of which has been won by working on small rich veins.

**TRAIL ORE RECEIPTS.**—A total of 7072 tons of ore and concentrates were received at the Trail Smelter, Consolidated Mining & Smelting Co. of Canada, from the 15th to the 21st of January inclusive. Twelve custom shippers contributed 1322 tons, the remainder coming from company mines.

The week's shipments in detail follow:

|                                  |      |

## NOVA SCOTIA

**COAL PRODUCTION RECORDS.**—The coal trade of Nova Scotia is booming. The Cumberland, Pictou, Inverness and Cape Breton Districts all show large increases over January, 1922. Indeed, the increase for the past month, would almost wipe out the 200,000 tons dropped last year. The British Empire Steel collieries in Cape Breton alone show an increase over last January of 175,000 tons. This concern aims at an output of 4,000,000 tons this year and considering the storms of the month of January which caused much idle time, a good beginning has been made.

**25,000 TON RAIL ORDER.**—Work has been commenced on the order for 25,000 tons of rails for the Canadian National Railways. This order will keep the rail mill busy until warm weather commences.

**BANKING COAL.**—The collieries at Sydney Mine are now operating by virtue of the banking of coal in preparation for shipment when Sydney harbour opens for navigation in the spring.

**LABRADOR GOLD REPORT.**—The press campaign to stimulate interest in the reported discoveries of placer gold in Labrador continues unabated. There is as yet no additional evidence in support of the truth of the statements made by those who are promoting the scheme.

**NO RED AFFILIATION.**—There is in the Nova Scotian collieries a decided feeling in support of the conclusion of U. M. W. A. headquarters that there must be no affiliation with the Russian Red organizations. The "radical" executive of the local miners' union have bowed to the decision of their headquarters with whatever grace they could muster.

Britain, whose prosperity depends essentially upon her export trade, is now profiting vastly from the industrial peace within her borders. Coal is the mainstay of her exports. First the great strike in the United States and now the French occupation of the Ruhr district have aided British coal exporters to regain their old markets and to capture new ones. The producers of iron and steel are commencing to share in this benefit.

With the new year there came into force the new administration of British railways in four great systems, the

great Western, the London Midland and Scottish, the London and Northeastern, and the Southern. It is anticipated that this will prove both economical and convenient, and it is expected that an immediate result will be the placing of large orders for much needed railway equipment.

The uses of Pyrex glass are being extended very rapidly. It is essentially a low-expansion boro-silicate glass of simple chemical composition, containing no metals of the magnesium-lime-zinc group and no heavy metals. Its coefficient of expansion is somewhat less than that of porcelain and is only one-ninth that of lead glass.

The Standard Conveyor Company has acquired by purchase all the rights, titles and patents pertaining to the well-known "Brown Portable" line of portable and sectional piling, elevating, conveying, loading and unloading machinery for the handling of packed and loose materials. This line of machinery has been manufactured by the Brown Portable Conveying Machinery Company at North Chicago for ten years. Until further notice the plant will be continued in operation by the Standard Conveyor Company, and all inquiries and correspondence regarding "Brown Portable" products should be addressed to Standard Conveyor Company, "Brown Portable" Products Plant, North Chicago, Illinois.

The Chief Consolidated Mine of Tintic, Utah, produced 4,437,000 ounces of silver in 1922, in addition to 19 million pounds of lead and 11,930 ounces of gold.

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

## A Complete Service—plus

You profit in two ways by Dominion Service:

First —In buying both oxygen and dissolved acetylene at the lowest prices obtainable;

Second—In securing a complete supply from one source,

—With positive assurance of highest quality,

—In modern improved cylinders, fitted with leak-proof valves,

—And your order is given the prompt, careful attention which it deserves.

Whether you buy oxygen and dissolved acetylene only once in a while, or in large quantities on contract, our plan of doing business promotes friendly relations which create a complete, smooth and satisfactory service.

We shall appreciate the opportunity of talking to you about Dominion Service.

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.      | Value.      | Year.      | Value.       |
|------------|-------------|------------|--------------|
| 1891 ..... | \$4,705,672 | 1906 ..... | \$22,388,383 |
| 1896 ..... | 5,235,003   | 1911 ..... | 41,976,797   |
| 1901 ..... | 11,831,086  | 1916 ..... | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

**THOS. W. GIBSON,**  
Deputy Minister of Mines,  
TORONTO, CANADA.

- Graphite by H. S. Spence.
- Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.
- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars** relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**
- Summary Report.** The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memoir 108.** The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

- Applicants for publications not listed above should mention the precise area concerning which information desired.
- The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.
- Communications should be addressed to **The Director, Geological Survey, Ottawa.**

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his claim, must perform a certain amount of work.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on providing that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, \$76,177,403; Lode Gold, \$105,557,977; Silver, \$55,259,485; Lead, \$18,330,575; Copper, \$166,393,488; Zinc, \$21,848,531; Coal and Coke, \$225,409,505; Building Stone, Brick Cement, etc., \$34,072,016; Miscellaneous Minerals, \$1,210,639; Making its mineral production to the end of 1920 show an

### Aggregate Value of \$734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for the year 1916, \$42,290,462; for the year 1917, \$37,010,392; for the year 1918, \$41,782,474; for the year 1919, \$33,290,313; 1920, \$35,543,084; 1921, \$28,066,641.

### Production During last ten years, \$336,562,897

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia.  
THE HON. THE MINISTER OF MINES,

# Flexible!

## -:- EDITORIAL -:-

*Let us remember that the [mining engineering] profession requires more than the mere honesty and personal integrity that every right minded man must have. It requires... watchfulness against fraud and... dangerous enthusiasm, — watchfulness indeed even against his own hope and enthusiasm.— J. B. Porter—1897*

### FOREWARNED — FOREARMED

The remarkable progress made by the Kirkland Lake gold field of Northern Ontario and the promise of its extension far eastward into the province of Quebec have already stimulated some thought and much talk about its future. The issue will rest principally, of course, upon what the prospector discovers and what the miner develops; but pending the decision to be reached in the newer parts of the fifty-mile belt of gold-bearing rocks, it is interesting to speculate upon the possible course of events. There is no doubt that those concerned with the guidance of the district's affairs in a broad way have already studied seriously its main problems of the future — transportation and power.

The logical route for the railway that will be required to open up this long gold field, should even isolated parts of it prove to be economically productive, is directly along the belt; that is a branch line from the Ontario Government Railway through the Kirkland field as far eastward as the mines may prove to extend. Within twenty-five miles, however, one comes against an invisible barrier, the inter-provincial boundary. How serious an obstacle this may be, only a test will prove. Moreover the territory on the Quebec side is naturally tributary to the Canadian Pacific Railway by way of the extension of its Temiskaming line northward to the Transcontinental line of the Canadian National Railways. This latter would, however, involve a new line one hundred miles long to tap the gold district, as against a line up to a length of, say, fifty miles from Kirkland that would traverse the gold district throughout. In the meantime it is interesting to know that the engineers of the Ontario Government Railway are already surveying the route for a branch railway eastward, and that the Canadian Pacific extension has been at least commenced.

If the newer parts of the gold district live up to their present promise they will require hydro-electric power far in excess of what can be supplied by present or possible developments on the Ontario side. The gold belt is only a few miles south of the height of land between the St. Lawrence and James Bay, and the comparatively small rivers on the Ontario side

within reach of the field can provide little more power than at present. On the Quebec side, however, there is potential power in plenty. The Quinze River, which constitutes the upper reaches of the Ottawa River, is the principal tributary of Lake Temiskaming and drains an area of 9,500 square miles extending two hundred miles eastward from that lake. The total power available from the fifteen falls and rapids that give the river its name is estimated at 93,700 horsepower. All these are on the eighteen miles of river between Lake Temiskaming and Quinze Lake, and some of them are said to be capable of cheap development.

The unnecessary and untoward delay in granting water-power rights to the Hollinger company has been due principally to lack of foresight combined with lack of executive ability in the public officials entrusted now and formerly with the disposal of that part of the public domain. The year's obstruction of development has cost the company, the province and the Dominion ten million dollars. Other companies have suffered in lesser degree. Canada and Canadians could have made very good use of that ten million dollars; it is a stiff price to pay for human failings. Nature will yield that unwon gold eventually; but we need it now.

We hope the future of the power supply for the newer field will be provided for with more foresight than in the former case. All are now well warned, and there will be no excuse for a lack of prevision. The waters of the Quinze River can provide power even for a second 'Rand, should we be fortunate enough to discover such a phenomenon in northern Ontario and Quebec.

### THE LIVING WAGE

In Great Britain just now, a good deal is being said and written anent what is called "the living wage." The big showing made by the Labor party at the last general election is, no doubt, responsible for the prominence that this subject has achieved in that country. For there can be little or no question but that, should the Labor party obtain a Parliamentary majority at any time, strong efforts would be made to establish a "living wage" by means of legislation.

Nor is it only in Great Britain that this question is likely to be prolific of ample discussion in the near future. As part of the announced program of a large section of organized labor and of members of the so-called progressive element in the newly-elected United States Congress, the living wage seems likely to be discussed even more in the future than in the recent past. Indeed, one United States senator, who has enjoyed a reputation for constructive ideas, has announced that he intends to propose a law guaranteeing railway workers a living wage, although the Transportation Act already contains rules under which it is possible easily to arrive at fair wages for railway employees. A proposal that is arousing so much interest in Great Britain and the United States is likely to be canvassed pretty extensively in this country, too.

In these circumstances, it is advisable to get some idea as to what the expression, a "living wage" means in the mouths of those who use it so glibly. It appears that a living wage from the organized labor standpoint means a purely imaginary amount that scientific budget makers think all workers in a given class of employment should have. In the case of the United States railway shopmen, their "economists" figured out that a living wage for shopmen ought to be something over \$2,000 annually. The United States miners have set similar standards for themselves—perhaps because they employ the same "economists."

In all of Labor's discussion of the living wage, what a given industry can pay is ignored. In other words the issue from Labor's standpoint is not what labor produces but what the workers would like to have in order to maintain a certain scale of living. This phase of the matter is very illuminating as being typical of the temper in which organized Labor, in so many lands, approaches the problem of wages today.

The Court of Appeals of the District of Columbia in handing down a decision declaring the minimum wage law of the district unconstitutional made some observations that constitute a valuable contribution to this whole subject, especially since so-called living wages inevitably become minimum wages. The court says: "A wage based upon competitive ability is just, and leads to frugality and honest industry, and inspires an ambition to attain the highest possible efficiency, while the equal wage paralyzes ambition and promotes prodigality and indolence. It takes away the strongest incentive to human labor, thrift and efficiency and works injustice to employee and employer alike, thus affecting injuriously the whole social and industrial fabric. Experience has demonstrated that a fixed minimum wage means, in the last analysis, a fixed wage; since the employer, being compelled to advance some to a wage higher than their earning capacity, will, to equalize the cost of operation, lower the wage of the more competent to the common basis."

No doubt, those who believe that it is the function of

the State to order the lives of all its citizens, from the cradle to the grave, will be little influenced by considerations such as these. But that the arbitrary fixation of wages is not merely undesirable, but impracticable, will be obvious to most people of common-sense who believe that there is still a place for ambition, industry and skill in the industrial world.

### RESEARCH IN MINES

The typical miner is an individualist. There are many evidences of this fact, as well as good and sufficient reasons for it, which it is not our intention to discuss at present. We wish to draw attention to one result of the miner's tendency to individualism that has the effect of retarding progress in the industry. This is his comparative neglect of organized, consistent scientific research.

Every miner must be a researcher to some extent, else he will fail in his work. The natural conditions surrounding his work are so infinitely varied that he must study them without ceasing and adapt himself and his methods to them continuously. He does this, in the main, unconsciously, having developed this habit of instant and complete adaptation from the very beginning of his mining experience. The miner, the foreman, the engineer and the manager, all have developed this faculty for coping successfully with new and unforeseen natural conditions as rapidly as they come to view. They are well on the way to being successful scientific researchers.

Here, however, the effort to control and direct often ceases. The miner is prone to stop his effort as soon as the pressure of immediate necessity is released. He does not of habit press forward into the unknown, to meet and solve difficulties before they actually force themselves upon his notice. He is noted more for his dogged determination in overcoming difficulties than for his skill in foreseeing and avoiding them. In this he has lagged behind his fellow-worker, the metallurgist.

A few weeks ago Professor Graham pointed out very aptly in these pages one of the chief obstacles the miner must overcome if he is to conduct experiments and improve his methods. The laboratory is of comparatively little assistance to him; his experiments must be made principally on the grand scale, in the mine itself. This is bound to be costly at times, and sometimes dangerous, so few are willing to risk it.

Happily the spirit of "laissez-faire" among our mining engineers is not now so nearly universal as it was even a few years ago. An increasing number are showing their practical appreciation of the utility of systematic work of investigation and are applying the idea to the development of more effective drilling and blasting, more economical stoping methods, cheaper tramming and hoisting, economy of air, better sam-

pling, more complete extraction of ore, and a hundred other practical problems. Canadian mining methods are rapidly gaining a character of their own, due to the efforts of those members of our profession who are actuated by the modern spirit of research. The number of these researchers and experimenters is still, nevertheless, all too small, and the Canadian mining industry will profit immensely when a much larger proportion of its engineers will have been converted to the researcher's faith.

### ALBERTA COAL

The largest producer of coal among our provinces now is Alberta. Alberta also contains by far the largest part of Canada's store of fuel, and it is confidently predicted by students of practical economies that as settlement proceeds this central part of our country will support a preponderating part of the total population, not only agricultural but also industrial. At that time Alberta coal will come into its own as the most important material factor in life on the great plains. Meantime there is a superabundance of coal there, and it requires all the energy and ingenuity the coal operators can summon to find a market for the product of their mines.

In their efforts to widen the market in Canada for the coal of Alberta and eastern British Columbia, the coal operators are working not only for themselves, but for Canada. To them is due in part the notable increase of exports over imports during the last twelvemonth. The less coal we import from the United States, the better shall we be able to meet our obligations in that country.

The Mines Branch of the provincial government of Alberta and the Western Canada Fuel Association both are doing a pioneer work of education in Winnipeg, which is at present the principal Canadian market within reach of our western coal mines on which American coal still has a firm grip. Both have established offices in Winnipeg in charge of competent engineers, under whose direction a propaganda is being conducted that bids fair to win the market for the Canadian producer. Incidentally, it appears that the high-grade semi-anthracite coal from eastern British Columbia will not only replace Pennsylvania anthracite in Manitoba coal bins, but will also prove more economical than the high-grade briquetted fuel it is proposed to make from the lignite at Bienfait, Saskatchewan.

The process of education undertaken by the Alberta Mines Branch and the Western Canada Fuel Association is bound to be slow; but we are confident that it will be sure, for they have not only a worthy cause, but one that will provide profit both for the miner and the consumer. We print today an article by Mr. Howard C. Ritchie, which illustrates the way in which

American coal has become entrenched in the Winnipeg market. A little judicious publicity of facts such as those cited by Mr. Ritchie will, no doubt, hasten the time when the prejudice against the use of Canadian coal that persists in certain quarters will be overcome, and full advantage will be taken of the wonderful store of fuel with which Nature has endowed the prairies and the neighboring mountains.

### EDITORIAL NOTES

The promoter of a bogus company pretending to manufacture a new electric water heater has been sentenced in Toronto to seven years in the penitentiary. He was convicted of issuing a false prospectus and of appropriating for his own use funds obtained from stockholders. We look forward with interest to the time when similar prosecutions and convictions will disturb the operations of the promoters of fake mining companies that infest Toronto and other Canadian centres.

The threat of an embargo on the export of Pennsylvania coal to Canada will impress upon Canadians dependent upon that coal more strongly than ever the advisability of developing our own sources of domestic fuel. This reminds us that the Federal and Ontario governments have not yet taken steps to ensure that the peat plant at Alfred, Ontario, shall be used next summer to turn out the 10,000 tons or so of excellent fuel it is capable of producing. If no private concern should undertake to operate the plant, it is certainly incumbent upon our public servants in Ottawa and Toronto to see that we get that 10,000 tons of fuel.

### INVITATION FROM A CANDID BROKER

Dear Sir: — Your name was handed me today,  
And I was told that you are in the way  
Of dabbling quite a bit in mining shares  
Of mines in Porcupine and otherwheres.  
And so I thought I'd write at once to you  
And state my case without too much to-do.  
Our mine, the Guinea, has twelve hundred feet  
Of subterranean workings trim and neat.  
We have a first-class lot of shafts and stopes,  
Assorted winzes, raises, cross-cuts, hopes.  
The latter are our staple and our stay,  
For nearly all our ore is mined away.  
But gold mine shares just now are all the fashion;  
The public's eagerness amounts to passion.  
So if by that same passion you are gripped,  
We can supply you with delightful script.  
And, take my word, there'll be no future fuss—  
Your cheque will close the incident for us.

J. C. M.

# Some Mines Of The Slocan

SILVER-LEAD-ZINC PROPERTIES CONTINUE  
TO BE PRODUCTIVE AND NEW ORE  
SHOOTS ARE BEING CONSTANTLY  
FOUND

By ROBERT DUNN

At a recent convention of mining men from British Columbia and the State of Washington one of the representatives of Washington said that it was the silver of the Slocan District that laid the foundations of the now prosperous city of Spokane. Not only is this true but it is an equally incontestible fact that the mineral riches of this section continue to contribute materially to the well being of these parts of this Province and of the State of Washington to which it is tributary.

What is known as the Slocan Mining Division, approximately 600 square miles in extent, situated in a region so mountainous that if flattened it would occupy twice as much space, figures largely in the mining history of British Columbia and its importance by no means lies solely in its past achievements.

## *East and West Kootenays*

The Slocan is a part of the Kootenay country, from which, since the first discoveries there of silver-lead-zinc ores, has come the bulk of the lead and zinc mined in Canada. In East Kootenay the production has been maintained almost entirely by three or four mines, and at present there is but one large shipper, namely, the "Sullivan," operated by the Canadian Consolidated Mining and Smelting Co.

West Kootenay, besides possessing a number of large producers, has always had some small operators and the Slocan and adjacent country has been, so to speak, the home of the small operator and the leaser. The number of independent shippers, leasers, and prospectors operating in this area greatly exceeds similar activity in any other part of eastern British Columbia. This is accounted for by the richness of the ore, the ease with which it is won, and the comparatively good transportation facilities. While not the most important provincial mining division economically, the Slocan has a history that throws an interesting sidelight on mining operations in the oldest lode mining area of the Canadian West.

## *Slocan Still Going Strong*

A. G. Langley, government mining engineer resident at Revelstoke, has compiled some illuminating notes on the Slocan, it being his contention that the wealth of mineral

of the mountainous Kootenays, with their rivers, lakes, timber and other natural resources, is not appreciated. He maintains, too, that the "silvery" Slocan is apt to be passed by with the careless reflection that it has produced in the past, but that all that was worth while has been taken. Mr. Langley declares that this is not true of any part of the immense region over which he presides as engineer, and in a special sense it is not true of the Slocan. There, he states, the prospector and the leaser have a happy hunting ground. In abandoned workings he may find lenses of ore that pay handsomely. It has been and is being done. New ground also is being opened up with good results and Mr. Langley would have the mining man warned that the time is not yet for the placing of the Slocan in the discard.

In this mining division there are three chief towns, Sandon, Silverton and New Denver, around which the mines are located. Sandon is situated in the narrow V-shaped valley of Carpenter Creek and is a mining camp pure and simple. The other two places are beautifully placed on the shores of Slocan Lake and a stranger might easily mistake them for summer resorts or fruit ranching settlements. As a matter of fact, however, they still play an important role in western mining.

## *Geology and Ores*

Geographically the Slocan can be briefly described as an area underlain by sedimentary rocks of the Carboniferous period, consisting of carbonaceous slates, limestones and some quartzites. This series of rocks has been intruded by dykes and stocks originating from nearby batholithic masses of granite. The ore deposits occur as lenses in fissure veins in the sedimentaries, sometimes near the contact with porphyry dykes and occasionally in the porphyry itself. The large bulk of the ore mined has been won from veins carrying good widths of ore, while exceptionally high-grade ore has been extracted at handsome profits from some of the smaller veins. The most common ore is argentiferous galena, associated with zinc blende in a gangue of siderite, calcite and quartz. The silver values are associated with tetrahedrite. The average run of the ore carries about 2 ounces of silver to the unit percent of lead.

The topographical conditions lend themselves to cheap mining. The hillsides are steep and covered with sufficient

New Denver, B. C., on Slocan Lake in the heart of the productive Slocan silver-lead-zinc district

timber for all mining purposes. Small water-power sites are available quite generally, as is also water for concentrating. With very few exceptions the ore-bodies can be approached by adit tunnels. Most of the producing properties are within easy reach of railway or lake transportation. Aerial trams are extensively used and are by far the best means of conveying ore from the higher altitudes. There are good roads where necessary, and the mountain trails are unsurpassed in any part of the district. As to the climate, Mr. Langley is authority for the statement that it is moderate, the winter not being excessively cold, while the spring, summer and autumn are ideal. The huckleberries, which grow in profusion on the hillsides, are a decided boon to the prospectors and others working in the hills.

#### *Silver and Lead*

In the early nineties the discovery of high-grade ores started a stampede to the Slocan. Many fine properties were staked, among them being "Slocan Star," "Payne,"

Mill of the Standard Mine, Silverton, B. C., part of plant of one of largest producers in the Slocan district.

"Reco," "Rambler Cariboo," and "Whitewater." Production started about 1892, since which time it has fluctuated in a rather remarkable way, due partly to irregular market conditions and partly to the available ore supply at different periods. The values recovered have been principally in silver and lead, as the ores are essentially silver-lead ores with zinc blende as an accessory mineral, although there are a number of properties in which zinc blende predominates. No doubt there would have been a larger zinc production had marketing conditions been more favourable.

Although large tonnages of clean galena have been shipped, the bulk of the Slocan ore has to be concentrated in order to separate the lead from the zinc and make as near as possible a clean lead and a clean zinc product. The result has been the erection of numerous concentrators, and today the Slocan can boast of some of the most up-to-date plants for the treatment of silver-lead-zinc ore by gravity and oil flotation processes that exist on the continent.

#### *Slocan Star Mine*

The names of properties that have produced from time to time are legion, but it may be interesting to know a little about the ones that have been outstanding in the history of the Slocan.

The "Slocan Star" mine, which has the record of being one of the leading producers in the camp, was staked on October 17th, 1891, by Bruce White. Mining operations at this property have probably extended over a greater number of years than those of any of the other properties of this division, resulting in the extraction of a large tonnage of silver-lead-zinc ore. The Byron N. White Company, which was incorporated in 1892, acquired and operated the

property and after a period of productive activity became involved in costly and protracted litigation with the Star Mining & Milling Company. The case arose over the "extra lateral" rights of an adjoining claim named the "Rabbit's Paw." In 1911 R. S. Lennie, of Vancouver, amalgamated the conflicting interests and incorporated a company under the name of the Socan Star Mines Ltd., which company operated the property up to 1917.

In 1918 a re-organization was effected and the property was transferred to the Silversmith Mines Ltd. Under the management of R. H. Stewart a large shoot of ore was encountered on the 1000-foot level, the development of which in subsequent years has again established the property as the leading producer in the Slocan. The length of this ore-shoot is between 300 and 400 feet with an average stoping width of about 4 sets of timbers.

The ore fed to the mill runs about 26 ounces in silver, 10 per cent lead and 7 per cent zinc. In order to increase the milling efficiency, the Ivanhoe mill was bought, remodelled and an aerial tram built connecting it with the mine. To give an idea of what this property has accomplished in past years, the following figures are submitted, which do not include the production during the last few years, which will add considerably to the total. Over a period of twelve years the following ore and concentrates were produced: Tons of crude ore shipped, 17,870; gross value \$1,291,728, net value \$933,398. Tons of silver-lead concentrate shipped, 15,594; gross value \$1,229,461, net value \$896,804. Tons of zinc concentrate shipped; 3,445; gross value \$154,061; net value \$45,170. Total gross value \$2,675,430; total net value \$1,875,372.

#### *Payne, Rambler-Cariboo, Ruth, Standard*

The "Payne" was staked in 1891 and is reported as being the first discovery made in the Slocan. It was located by Eli Carpenter and John L. Seaton. Up to the end of 1904 this mine produced 50,000 tons of silver-lead averaging 68 per cent lead, and 120 ounces of silver per ton, together with 6000 tons of zinc blende, the aggregate value of which amounted to \$5,000,000. The dividends paid reached the grand total of \$1,438,000 or 28.76 per cent. This property has been lying idle for a number of years.

Among other steady producers the "Rambler-Cariboo" has a splendid record, has paid handsome dividends, and is still an active property.

Sandon, B. C., a typical Western mining town, situated in the midst of the mountains of the famous Slocan silver-lead-zinc district.

The "Ruff" mine near Sandon, after a period of productive activity, remained closed down for a number of years. Recently leasers cleaned out some of the old workings and were rewarded by striking some exceptionally fine ore. This year the property was acquired by a Vancouver syndicate and a small crew of men were put to work. The results so far obtained have been highly satisfactory.

The Standard mine, near Silverton, which has paid \$2,700,000 in dividends, was of more recent discovery than any of the properties above mentioned, and it was not until 1911 that it became an important producer. Credit is given to George H. Aylard for making the now famous mine out of this prospect. The surface showing was not considered in any way remarkable and those who examined it little thought that it would lead to the development of one of the largest ore-shoots ever discovered in the Slocan. Mr. Aylard, however, had other ideas and with dogged persistence and untiring energy developed a mine that turned out to be one of the largest and most profitable producers in this division. The main ore-shoot was developed between the No. 3 and No. 6 levels. On the No. 5 level it was 400 feet long and up to 20 feet in width of clean galena, besides an equal thickness of concentrating ore. The mine is still being worked and a considerable tonnage of zinc ore is being extracted by leasers.

#### *Queen Bess Mine*

The above mentioned properties are only a few out of a great number that have been developed in this division. There are others with just as good, if not better, records; in fact there is still one property that must be mentioned, for it demonstrates what some of the old abandoned mines may have in store for those who have the nerve to open them up and spend a little money on dead work. The mine in question is the Queen Bess. In about 1916 Clarence Cunningham acquired this property, which had been lying idle for a number of years. With a handful of men he opened up in a short time an exceptionally fine shoot of clean lead ore carrying high silver values. In about three years he made a profit of something like a million dollars.

Things are looking up in the Slocan just now, metal prices are good, smelting rates are lower, and for the first time in the history of British Columbia except during a short period of abnormal conditions produced by the war, zinc ore and concentrate are being accepted by the Trail smelter. The shipper receives payment for the zinc as well as for the silver values.

New discoveries are constantly being made and will continue to be made in the Slocan for many years to come, and taking all things into consideration we can look with confidence to the future of this richly mineralized area.

In view of the present and proposed activities in the manufacture of asbestos in Canada, the use of asbestos-coated metal for roofs and siding has a renewed interest.

The steel base is covered with a mixture of asphaltic material and asbestos fibres, which protect the metal against any ordinary corrosive action. Though the asphalt is combustible, it will not ignite unless it is subjected to an intense heat over a considerable area.

The tonnage of ores passing through the Suez Canal in 1922 was approximately 1,450,000 tons, as compared with 1,560,000 tons in 1913, the record year. Manganese ore, mainly from India, comprises the major part of this tonnage. Zinc ore shipments were about 200,000 tons, principally from Australia.

## LETTERS FROM READERS

### *Madagascar Graphite of Good Quality*

To the Editor,

Canadian Mining Journal.

Sir:—In the December 8th, issue of the *Canadian Mining Journal* you published an article entitled "Canadian Graphite to Lead in the World's Market" by Mr. H. P. H. Brumell, in which the statement was made that the Madagascar graphite has been found unsatisfactory for the manufacture of crucibles, the most important of all uses to which graphite is put.

As this information was contrary to any we had on our files, we made further enquiries and have received, through one of the Government Trade Commissioners, a statement from the Imperial Mineral Resources Bureau, London, S. W., to the effect that they have no information that Madagascar graphite is unsuitable for crucibles, but that on the contrary, to their knowledge, it is being used in preference to Ceylon graphite owing to its better quality and grade.

As the dissemination of information of this kind is detrimental to the development of Canadian resources, we shall appreciate it very much if you will have this statement corrected.

F. C. C. LYNCH.

Natural Resources Intelligence  
Service, Ottawa.

## LIME IN UNITED STATES IN 1922

About 3,528,000 short tons of lime, valued at \$33,057,000, was sold in the United States, including Hawaii and Porto Rico, in 1922, according to an estimate made by the United States Geological Survey, from reports received from the principal producers. This quantity is more than 39 per cent. greater than that sold in 1921 and only 1 per cent less than that sold in 1920. The average value per ton in 1922 is estimated at \$9.37. In 1921 it was \$8.83 and in 1920 it was \$10.52.

The sales of hydrated lime in the United States in 1922 were estimated at 1,125,300 short tons, an increase of 42 per cent. over those in 1921 and the largest yet reported. Of the 31 States that reported an output of hydrated lime in 1922 only three showed a decrease. The estimated value of the hydrated lime sold in 1922 was \$10,850,000, an average value per ton of \$9.64. The average value in 1921 was \$9.36. The demand for lime was obviously better in 1922 than in 1921, but producers report that the market was very irregular. Prices fluctuated greatly throughout the year, but showed a decided downward trend. Lime for construction undoubtedly made the largest increase in production, and chemical lime also increased appreciably, but it is doubtful whether agricultural lime made any increase whatever.

Chemical lime showed decided improvement in demand during the year, according to the manufacturers of lime of this class, but not so decided an improvement as construction lime. Though increases of 5 to 70 per cent and exceptionally of 125 and 160 per cent were reported there were more reports of fair demand and about the same demand as in 1921 than in the reports for construction lime. The last half of the year appeared to be a time of great improvement in the chemical lime trade 1922. The sales of refractory lime (dead-burned dolomite), used in patching and lining basic open hearth furnaces, increased from 107,664 short tons in 1921 to over 300,000 tons in 1922.

# Mine Accidents in Nova Scotia During 1922

INCREASED ACCIDENT RATE DUE IN PART TO  
NEGLIGENCE OF MINERS—LAWS AND  
PREVENTIVE MEASURES GOOD

by JOHN MOFFATT

The mining industry of Nova Scotia has had a bad year for accidents. The figures for the whole of 1922 are not yet available, but Cape Breton's fatal accidents were much more numerous than during 1921. In the face of so much work done and money spent in 1922 to avoid accidents, it is not encouraging to have to report an increased rate. But while the individual fatalities were greater, it is cause for thankfulness that our collieries have not been visited by catastrophies such as mine explosions. It requires constant vigilance to prevent these, for there is scarcely any coal mine of any depth, that has not all the elements of an explosion, if these are permitted to exist and get together. This is especially true of the larger collieries of Nova Scotia. Apart from fatal accidents the non-fatal were one per cent. less than in 1921.

## *Mine Accidents in the United States*

There seem to come periods when, do what we will, the accident rate keeps climbing up. The United States coal industry had had such a period in 1922 as well as Canada. President Rush N. Hosler, recently addressing the Coal Mining Institute of America on the dangers of mining, said that "one in every five employees in and around the mines of Pennsylvania is injured every year severely enough to require medical attention, this injury being anything from a slight wound requiring a surgical dressing to the loss of life. One employee in every two hundred and fifty engaged in haulage is killed each year and annually one brakeman and one trip rider in every one hundred and twenty engaged in that work likewise is killed." When made in this way, such a statement is most startling and cannot fail to rouse mining men and cause them to take a more active interest in mining accidents, and their causes.

## *Haulage Accidents One In Six*

Out of about fifteen hundred men on the haulage systems of Cape Breton collieries, five men lost their lives during 1922. This is away above the average of past years, and it serves to emphasize the danger to a class of men who are either entering on life or in the prime of it. In all two hundred and forty three accidents occurred in this class during the year, or one in every six. The cause of these accidents arises from narrow, unlighted roadways, from the high speed of trips and from the still higher speed of mine cars breaking away from haulage ropes and rushing down heavy grades. The darkness of the mine conceals the oncoming box, and its noise is usually the first indication that a breakaway has occurred. It may be then too late to escape. Derailing switches, stop blocks, and other devices are used against such occasions but with accelerated speed a run-away trip brushes these aside or jumps over them, keeping on its course until brought up at the bottom of a deep or headway.

## *Accidents at the Face*

Accidents from the falls of rock and coal head the list at 333, but although numerically higher they are, according to the number of men employed less than that of the class handling mine cars. It is probably here that the largest reduction could be made, as it is very often owing to too great haste to get a large amount of coal filled (as wages

depend on tonnage sent up) or to faulty judgment that many of these accidents occur.

The labor unrest of the past few years has also contributed to the number of accidents. Mine officials report that it is difficult to get the miner to keep his spraggs up against the coal face. The workmen fail to see that the violation of laws made for their own protection, and lax discipline on the part of mine officials who fear friction from too strict enforcement of the law, reacts on themselves by an increase in the number of accidents. It is the common opinion of those who have made inquiry into the causes of accidents that hearty co-operation between the mine officials and the miners would greatly reduce them.

## *First-Aid Stations not Sufficiently Used*

Another serious feature to be noted during the year was the large increase of septic cases. With well equipped first aid stations at each colliery there should have been a large decrease in this class of accident and also in the length of time the septic cases should have taken to heal. But it was otherwise.

Alberta miners last year applied to the Government for the establishment of first-aid stations at all collieries. But if, when these are established, workmen will not use them, then compensation should be withheld from all, both there and here, who will not take the means at hand to prevent a cut or small wound from turning to blood poisoning. If coal companies are by law compelled to build first-aid stations and equip them, the same law should have something to say about the miner, who, because he refuses or neglects to be treated there, permits a slight accident to develop into a serious state and so prolongs the time of compensation.

When we take into account the time and money spent in trying to prevent accidents, and in investigating them after they do occur, we fear that results are not what they should be. The larger coal companies maintain a safety department with a staff of highly trained inspectors who enter the mine daily for the purpose of detecting dangerous conditions, places and practices and bring these to the notice of the busy mine officials. These men investigate all accidents and report on them. In addition the Compensation and the General Superintendent's Departments scrutinize the causes of all accidents. There is no let-up, no lying down on the job, and the coal companies of Nova Scotia are determined that there shall be none. So far as is humanly possible the staffs of our coal mines are preventing accidents. It is up to the miners to co-operate.

A new coal field, which it is reported will add enormously to Great Britain's coal wealth, is being opened in the Dukeries district of Northamptonshire. Six pit shafts are to be sunk, some of which have been commenced. A new company has been formed with an initial capital of £500,000 to develop coal deposits in Kent.

The prospecting around Guebwiller, near Mulhausen, Haut-Rhin, France, for petroleum is being carried on very actively and definite results are expected soon. A new oil sand has been found near the original well and drilling will be started at once.

## THE UPPER CRITICAL SCORE\*

FIRST MEASUREMENT OF THE HIGHER AS WELL AS THE LOWER LIMITS OF INTELLIGENCE, BEYOND WHICH IT IS NOT PROFITABLE TO EMPLOY APPLICANTS FOR A PARTICULAR TYPE OF JOB

A rough measure of the brightness, or mental alertness, of an applicant, by means of a standardized mental test, has long been recognized as one of many possible sources of information for use in personnel selection. Early tentative attempts to use this test technique in employment procedure, sometimes met with anomalous results because it was not recognized that, for some types of employment at least, an applicant may be too intelligent.

In affiliation with the Carnegie Institute of Technology, Pittsburgh, a group of twenty-seven companies of national scope established, in June, 1916, the Bureau of Salesmanship Research, now the Bureau of Personal Research. This Bureau was to pool the experience of the co-operators to evaluate their current procedures, and to devise and try out new ways of selecting and developing salesmen. The first year's work, under Walter Dill Scott, issued in a volume of "Aids in Selecting Salesmen," including an improved personal history record, or application form, a model letter of reference to former employers, a guide to interviewing which helped the interviewer to focus his attention on essential traits and to record his judgments quantitatively,\*\* and a set of five psychological tests with full directions for giving and scoring.

Among these tests was a group intelligence examination, a forerunner of Army Alpha. It was given to various groups of salesmen and sales applicants, and their scores were checked against actual success as measured by amount of sales. Among the men so examined, was a group of 40 salesmen for a food products company. To the dismay of the research workers, when the intelligence test scores were compared with the men's sales-production records, the correlation was almost zero. This appeared to be a severe indictment of the test as a measure of intelligence.

Then came the War, and with it a vast experience in personnel classification and intelligence examining. The psychological tests proved their worth in the Army as indicators of mental alertness. So when C. S. Yoakum, with this background of Army experience, in 1919, assumed direction of the Bureau of Personnel Research, he knew that the intelligence test methods were valid, and he sought another explanation of the riddle in the findings of 1916. Taking the same data, he computed the correlation between test scores and length of experience with the company. The correlation was not zero. It was negative, —40. The brighter the salesman, the quicker, as a general rule, he left the employ of that concern.

Yoakum repeated the experiment with 76 salesmen of this same company, using the best available adult intelligence examination. The correlation of test scores and length of experience was —46. A job analysis revealed that the work was largely of the routine, order-taking sort. The pay was not large. Chances of promotion were slight. Only the more stolid men were content to remain long enough to get valuable experience and build up a creditable sales record.

Examining the intelligence scores again, it was apparent that there is an upper limit as well as an anticipated lower limit. Within this range, the chances are large, that an applicant for a position with this concern will make good. Below this zone he will probably fail for lack of ability. Above it, the probabilities are are that he will not remain long enough to learn his work thoroughly and make a good showing. The psychological test had, after all, been a valid measure of mental alertness. The need had been for a determination of its range of utility.

This range varies for different kinds of salesmen, as well as for different occupations. In many jobs it has been shown that there is no upper limit to the optimal intelligence score; but studies of policemen, salesmen, and many types of operatives and clerical workers, where the task is essentially routine, have shown how necessary it is to keep an eye on the upper as well as the lower critical score. Research on the utility of psychological methods in employment and placement is but one of many scientific approaches to problems of industrial personnel. Taken as a whole, the scientific study of the human factor may prove as important to the next era of industrial progress as research in the physical sciences has proven hitherto.

## U. S. BUREAU OF STANDARDS

During the past year the activities of the Bureau of Standards at Washington have included numerous investigations of interest to the metallurgist as reported by the Director in the *Journal of the Franklin Institute*. Among these are a study of methods for the analysis of gases in metals, the determination of thermal stresses in car wheels, and the rust resistance of alloy steel. Particularly important work has been accomplished by the research associates in metallurgy sent to the Bureau by various manufacturers.

As in other work in connection with ceramics, the practical problems have been particularly stressed. Tests have been conducted of tableware and window glass, the best types of American clays to use in paper-making have been determined, and the comparative value of various ceramic materials for different purposes has been investigated.

The making of optical glass in the Bureau's laboratory has been carried on very successfully, a great deal of first class glass in the form of lens blanks and finished lenses having been supplied to other branches of the government, particularly to the Navy Department.

Specifications are being prepared for refractories, such as the fire brick in boiler furnaces, and work is under way which will lead to the improvement of enamelled metal products.

During 1922 the production of beehive coke in the United States increased 45 per cent. over 1921, and by-product coke, 44 per cent. The relative quantities, though differed much—8,033,000 tons of beehive coke and 28,493,000 tons by-product. The recoveries of by-products were approximately as follows: tar, 365,000,000 gallons; ammonium sulphate, 964,000,000 pounds; gas 447,000,000 M. cubic feet; crude light oil, 111,000,000 gallons.

The mill of the Modder Deep mine on the 'Rand, South Africa, is to have an oil flotation plant to concentrate the sulphides from its current sand product. It is expected that this addition to the mill will give a net profit of 8d. per ton of ore.

\*Research Narrative No. 49, by Dr. W. V. Bingham, Director of Co-operative Research, Carnegie Institute of Technology.

\*\*This form later became the Scott Rating Scale of the Army.

# Re-Tinting the Rainbow

By ALEXANDER GRAY

Three outstanding events of past week are: First, the announcement of Mr. Curry that the Ontario Government bill for the regulation of the sale of securities is designed, principally, "to insure the proceeds of stock sales being used to develop properties instead of being frittered away in promotion, so as to see that a company gets away with a reasonable chance of success, but without guaranteeing success." Second, that there is to be a "wild scramble" for Labradorean gold, and 2,000 areas of 320 acres each have been allotted by Newfoundland. Third, that Americans have obtained a concession to work the Amur gold fields, the Soviet Government to have 18 per cent. of the gold recovered for thirty-five years and the plant to revert to the Government at the end of that time.

## *The Proposed Law*

Taking Mr. Curry at his word, we are to have a speculative revolution. Promoters' perquisites are to be ruthlessly dealt with; "fifty-fifty" brokerages are to cease; a greater percentage of the capital raised by appeals to the public is to go toward exploration and development.

It is not intimated whether the "Commissioner" to be created by the Sales of Securities Act is to have discretion in limiting capitalizations or in the disposition of vendor considerations. No restrictions, as things are constituted, are imposed upon initial nominal issues, for which the usual registration fees will be charged. But how the law-givers are going to prevent promotion and distribution costs from being diverted, is something the most circumspect governments have not yet been able to provide for. Stipulations that shares shall not be sold except at fixed prices and that commissions shall be so much never have availed where it is possible to include all these in vendor considerations, or by other means familiar to promoters. Agreements as between original owners, intermediaries, and incoming interests are susceptible to so many diversions, it will take more than animadversions by the "Commissioner" to give companies granted an official status, "without recommendation" a "reasonable chance of success". Human expectations as capitalized in ordinary mining ventures require a restraint that mere legislation cannot impose. Sanction without certification is in the nature of passive resistance to established practice.

## *Bushels of Gold!*

No less emergent is the impending stampede to Labrador. The Newfoundland authorities have not affirmed or denied the existence of "another Klondike". They are reported to have granted rights to over 640,000 acres of what may or may not be placer ground; and large numbers "are being held back from this latest Eldorado only by the rigors of a Labrador winter." Wm. H. Taylor, of Newfoundland, is quoted in New York as saying that "the anticipated boom has led to speculation in claims." This hardly expresses the situation. At least one Montreal company had \$150,000 in its treasury two weeks ago. Available space on vessels chartered has been exhausted. Expeditions are being outfitted. More schooners are being built. The "scramble" for the "gamble" has reached proportions not generally understood, unmindful of the adverse features of the speculative game.

Why Newfoundland authorities have permitted flotations and flamboyant statements to go broadcast unchallenged, before the areas have been tested, is not commented on by the daily press. The pot of gold is at the end of the rainbow, in contact with the aurora borealis, according to those who have made the public pay for what may be a most distressing experience.

Without minimizing the profits derivable from "another Klondike", Labrador conditions are decidedly different and grab samples are not sufficient warrant for what has happened. When the Fort Norman "gusher" stirred up the adventurous, the Dominion Government took the precaution to prevent "blanketing" and to see to it that those unprepared for a sojourn in the sub-Arctic were turned back. So far as known, nothing of this sort is arranged as regards Labrador. How much gold-bearing gravel there is, Newfoundland does not know, nor even if there is any. Town lots in the suburbs of the Hudson Bay Post at York House may be a sounder investment than a great deal of what is being dealt with on a "co-operative" basis — \$200 down and the balance in placer gold that may not exist.

Of course comment is unavailing where the allurements are so transcendent and verification of them must await actual examination and results. However, the risk is too one-sided, and Newfoundland officials are not without responsibility. Not for an instant will any well-meaning person attempt to discredit any bona fide development of the kind. It may be a reversion windfall to Newfoundland, but if the "retreat from Moscow" is duplicated, who is going to bear the blame and punish promoters — if they are punishable?

## *Russian Gold*

This brings into this discussion of passing events the American adventure on the Amur, through the favor of the Soviet Government of Russia. For thirty-five years the concessionaires are to pay 18 per cent. of the gold recovered. Provision that plant will go to the Government at the expiration of the period will naturally negative itself; for the chances are there will be no junk dealers in the vicinity at that time. It may be perfectly true, as Mr. Tyrrell told an audience the other day, that the pre-Cambrian formation probably extends into the Polar regions; but it will be some time before prospectuses having to do with those are given display space in the press. Besides, 18 per cent. of the net is an impost few gold ventures could survive, unless the gold is as plentiful as it is alleged to be in Labrador, whither Canadians, Americans and Australians, according to Mr. Taylor, are to go "flocking" — perhaps with wool already shorn.

That there is gold in Labrador and in the Amur country, is not questioned. Wherever glacial action did not complete the denudation, there is likely to be alluvial gold. To find it will require more than light lunches and a change of socks and moccasins. As for the Amur, every decade or two Russian riches have bestirred London, and if New York avails of the latest concession it will be just as well to submit to the most stringent regulations Mr. Raney can impose. Those who prefer the rainbow tips to colors close at hand may chase them if they will; but they have a de-

oddly futuristic appearance to the majority of art critics.

\* \* \*

640,000 acres of Nuggets! Labrador the Golden! Russian Rivers Running over Beds of the Precious Metal! and no Mr. Raney to shepherd the gathering flocks!

### BOOK REVIEWS

**BRIQUETTING** — by Albert L. Stillman — Chemical Publishing Co., Scranton, Pa. — 466 pages, fully illustrated.

This treatise on the principles and practice of briquetting is the first attempt by a writer in English to compile and arrange the mass of information now available about this increasingly important industrial operation. A vast amount of fuel is now briquetted annually, such as the culm or slack of anthracite and bituminous coal; lignite; brown coal and peat in Europe; flue dust from blast furnaces; fine ore of many kinds, such as iron and zinc concentrates; scrap metal such as steel, iron, brass and aluminium, and even sawdust for fuel. Briquetting overlaps of course, with operations such as sintering, which are not treated in this volume.

After a short discussion of the raw materials to be treated, the various types of briquetting presses are described. The application of these devices in practice is then described, particular attention being paid to plants in the United States and Canada.

The volume illustrates the modern tendency to devise ways and means of using what were formerly waste products. The material collected by the author is excellent, and we hope that in a future edition he will be able to present it with less evidence of hurried publication.

**ELEMENTS OF MINING**, by George J. Young—McGraw-Hill Book Co., 370 Seventh Ave., New York—671 pages and 282 illustrations—Price \$6.00.

This book was first published in 1916, and the 1923 edition is completely revised and in part rewritten. One's first impression of the book is that its field is so broad that the matter must be so elementary as to be uninteresting to any but the beginner. A further acquaintance demonstrates, however, the fact that Mr. Young has succeeded in presenting not only information but live ideas on a very wide range of subjects, and withal has preserved a balance among the various sections of his subject matter that is rare in general text books written on this continent.

There is well illustrated in this book a tendency among technical writers that is, happily, rapidly becoming the vogue. Mr. Young's statements are, in the main and of necessity, couched in general terms without the support of the substantiating data. But he has interposed frequently and with unusual discretion actual data, in such a way as to lighten rather than to burden the text. Another valuable tendency illustrated here is the inclusion in this technical treatise of a discussion of the values of ores, relative as well as absolute, and their sale, the cost of typical mining operations, and the fundamentals of mine organization and operation and accounting.

The illustrating of the book is unusually well conceived. It contains little but diagrams, and each of these is made to serve a distinct and useful purpose. The perspective diagrams illustrating stopping methods are especially good.

Mr. Young's book in its revised form merits the attention not only of those who are commencing the study of mining but also of the vast majority of practicing mining engineers whose preoccupation in special phases makes advisable an antidote in the form of a good, general treatise.

### HOW TO FIRE SUBSTITUTE FUELS

Many a householder who has experienced great difficulty in trying to burn the substitute fuels thrust upon him this winter will welcome a pamphlet just issued by authority of the Dominion Fuel Board telling him just how to proceed to get the best results. The Mines Branch at Ottawa has been experimenting for months with these auxiliary fuels in ordinary domestic furnaces, and the pamphlet now issued tells what they have found out. The fuels tried out were soft coal, pea-size anthracite, gas coke, 72-hour nut coke, Welsh anthracite and peat.

A feature of the experiments was that the use of two of these fuels together often gave better results than one used alone. Complete directions are given for building the fire, for replenishing it and for regulating the drafts. Chemical analyses are also published of each fuel, showing its comparative heating value, ash content and other constituents.

Particular interest attaches to the directions for using soft or bituminous coal; for, the Canadian householder, in the great majority of cases may find it necessary to use soft coal for the remainder of this winter. This fuel, the pamphlet points out, is differentiated from anthracite in having a much higher percentage of volatile or gaseous material. Its heating value, however, is nearly 10 per cent greater than that of anthracite, but it must be fired differently from the latter to get best results.

Care must be taken to see that the gases that come off are burned. In putting on more fuel, part of the old fire must be left uncovered to ignite these gases and the grid in the fire door must be left open to supply air so that the gases will be burned. A soft coal fire also has to be poked more to break up the caked fuel mass in order to permit of complete combustion. The unconsumed gases deposit a layer of soot on the interior of the furnaces and the flues, and this should be cleaned off daily to get the best heating results.

The pamphlet is written in clear non-technical language, and should be read carefully by every householder. It is being widely circulated and coal-dealers are being given a supply for free distribution to their customers. Copies can also be obtained on application to the Department of Mines, Ottawa.

Last year there were launched in Britain 1,031,081 tons of merchant vessels, which is 41.8 per cent. of the world's total, as compared with 58 per cent. in 1913. The most noticeable change during the year was in the United States, whose new tonnage fell from over a million tons in 1921 to 119,138 tons in 1922. Canada built only 17,012 tons, accounted for mainly by one large steamer launched at Port Arthur.

The Canadian Ingersoll-Rand Co. now have available for distribution circulars describing the mechanism and use of their Little Tugger Hoist (No. 4056); the IRLP Shank and Bit Punch (No. 4055-C); the "Ingersoll-Rand" Air-line Lubricator (No. K-218); the "DriAir" automatic water trap; and the Cameron centrifugal boiler feed pumps (No. 7056-C). These circulars can be had on application by any wishing them.

# Alberta Coal in Winnipeg

PUBLIC SCHOOL BOARD BUYS POORER IMPORTED COAL  
AT HIGHER PRICE

By Howard C. Ritchie \*

Early in October, the Directors of the British Empire Exhibition, which is to be held in Wembley, England, next summer, met for the purpose of arranging for the purchase of necessary supplies, and very much to the surprise of the Canadians on the Board, it was announced that timber and flour from foreign countries would be imported. Mr. Grant Morden asked why Canadian flour and timber would not be bought, and pointed out that the purpose of the Exhibition was to promote better trade relations within the Empire. The Manager explained that Canada could not produce good bread from its own wheat, and as for timber, it was impossible to get timber in Canada suitable for building fences at Wembley. To support his contention, he passed around a sample of what he described as a "very inferior sample of Canadian Spruce." As a protest against this absurd libel on good Canadian products, Messrs. Robert Donald and Grant Morden resigned from the Board. The Canadian papers from coast to coast used columns of space to prove our wheat was second to none, and our timber was not only suitable for building fences, but might even be used for the construction of houses. The hue and cry raised over this incident was heard throughout the Empire and resignations and explanations followed as a matter of course.

About this time the Winnipeg Public School Board awarded the contracts for supplying coal to the schools. 7,200 tons of American coal were bought for approximately \$95,250.00 and 950 tons of Canadian coal for \$7,820.00. Nothing was said in the Press about patronizing foreign mines when Canadian mines were idle for want of business. None of the School Trustees resigned as a protest against these purchases, and the public assumed the School Board had bought in the best market. But did they?

## A Libel on Canadian Coal

This article will deal with all tenders received, and try to prove, to the satisfaction of the reader, that the rate-payers of Winnipeg are very much out of pocket by these purchases of American coal, and that the action of the Board in ignoring the majority of tenders for Canadian coal is a serious libel on our coal industry which will prejudice other buyers against our good coals. It is unfortunate that the subject cannot be dealt with briefly; but there are so many figures to be considered, and the arguments used to prove that Canadian coal was worthless for this purpose are so nearly unique that in justice to the bidders, (and incidentally the School Board) it is necessary to submit a lengthy analysis of the subject.

The following is a list of all the offers of Canadian coal received, and some of the prices asked:

|                     | Per Ton |            |
|---------------------|---------|------------|
|                     | \$11.75 | to \$12.80 |
| Cadomin .....       | 12.45   | 13.35      |
| Michel .....        | 9.00    | 10.10      |
| Pembina .....       | 7.90    | 8.50       |
| Coal Valley .....   | 9.90    | 10.85      |
| Corbin .....        | 11.00   |            |
| McLeod River .....  | 10.85   | 11.90      |
| International ..... |         |            |

|                          | Per Ton |            |               |
|--------------------------|---------|------------|---------------|
|                          | \$10.85 | to \$11.95 | "Not desired" |
| Bellevue .....           | 10.50   | 12.25      | " "           |
| Greenhill .....          | 12.35   | 12.45      | " "           |
| Hillcrest .....          | 12.15   | 12.45      | " "           |
| Luscar .....             | 11.55   | 11.95      | " "           |
| Mohawk .....             | 12.50   |            | " "           |
| Coal Creek .....         | 11.25   | 12.55      | " "           |
| McGillivary Creek .....  | 12.25   |            | " "           |
| Foothills .....          | 9.00    |            | " "           |
| Black Diamond .....      | 7.80    | 9.00       | " "           |
| Dinant .....             | 8.50    | 10.20      | " "           |
| Bush Mine .....          | 8.25    |            | " "           |
| Atlas .....              | 10.20   | 11.00      | " "           |
| Sterling .....           | 11.00   | 11.70      | " "           |
| Minehead .....           | 7.45    | 9.20       | " "           |
| Rosedeer .....           | 9.15    |            | " "           |
| Lakeside .....           | 9.55    |            | " "           |
| Monarch .....            | 9.45    |            | " "           |
| Elgin .....              | 8.50    |            | " "           |
| Kneehills .....          | 6.50    | 9.00       | " "           |
| Hygrade .....            | 7.20    |            | " "           |
| Western Gem .....        | 8.50    |            | " "           |
| Western Commercial ..... |         |            | " "           |

Thirty Canadian coals, representing almost every field in Western Canada, were offered at prices varying from \$6.50 for Hygrade to \$13.35 for Michel, delivered in the school basements.

The tenders were turned over to the Chief Operating Engineer of the School Board for tabulation and to calculate the relative values of the various coals at the prices asked. Col. Mitchell, Commissioner of Building and Supplies, has kindly furnished a copy of the report of the Chief Engineer, and the figures quoted here are taken from that report.

## Canadian Coal Used Elsewhere

Of the thirty Canadian coals offered, twenty-three of them were marked "Not desired" and were therefore not considered when awarding the contracts. Why they were "not desired" is not stated, but it is assumed that in the opinion of the Chief Engineer they were "inferior Canadian coals, not suitable for heating school buildings". In this list are several varieties that are commonly supposed to be good coal, and have been purchased by School Boards in other cities for years. Luscar coal is being used to heat the schools and collegiates of Moose Jaw this season. The Secretary of the Board writes that it gives "complete satisfaction to the Trustees." McGillivary Creek coal is being used in the Calgary schools and has been found "very satisfactory." The Regina School Board has used Bellevue, Hillcrest, Greenhill and McGillivary Creek coals and they have all given "splendid satisfaction." The Brandon schools have been heated with Canadian coal for several years and they have "proved more economical than American coal."

Yet none of these coals were even considered by the Winnipeg Public School Board as being worthy of consideration. It was not a matter of price or quality. They were simply not allowed to compete for the contracts. This liberal application of the blue pencil reduced the competition to the seven Canadian coals at the head of the list. Three of these were purchased in small quantities for "test purposes," so they were safely disposed of. 350 tons of Pembina were purchased

\* Secretary of the Western Canada Fuel Association.

for use in Spencer boilers. In the past, American anthracite was used for this purpose, but it was found that Pembina was easier to handle and proved more economical, so those school caretakers who asked for Pembina were supplied with it, although we understand some schools with Spencers are still using an-

where they are subjected to much more severe tests than the heating of school buildings. Cadomin, International and Michel were given a value below the analyses submitted with the tenders. The Chief Operating Engineer's tabulation of the steam coal tenders is here given:

| Mine                   | Grade | Stated heat value | Heat value allowed | Price   | Comparative value                                |
|------------------------|-------|-------------------|--------------------|---------|--------------------------------------------------|
| Pembina .. . . .       | M. R. | 14,300            | 14,200             | \$12.95 | Lowest tender on Pocohontas used as base figure. |
| Pocohontas .. . . .    | M. R. | 14,200            | 14,200             | \$13.25 | \$12.95                                          |
| Youghiogheny .. . . .  | M. R. | not stated        | 13,700             | \$12.55 | \$12.50                                          |
| Cadomin .. . . .       | M. R. | 13,640            | 12,250             | \$12.05 | \$11.22                                          |
| International .. . . . | M. R. | 12,500            | 11,620             | \$11.90 | \$10.60                                          |
| Michel .. . . .        | M. R. | 14,500            | 13,500             | \$12.45 | \$12.30                                          |
| Pocohontas .. . . .    | Slack | 14,300            | 14,300             | \$12.50 | \$12.50                                          |

NOTE: — Tenders on all other kinds of Slack coal were rejected, so no comparisons were made on this grade and a contract amounting to about \$25,000.00 was given without any competition from any other variety of coal.

anthracite, which costs almost twice as much and gives no better satisfaction.

### Requirement of Tender

This left three Canadian coals to compete with two American coals, so it will not be hard to examine the bids carefully.

The Board asked for tenders for supplying steam coal equal in heat value units to 5,200 tons of West Virginia Pocohontas mine run coal; also steam coal screenings equal in heat value units to 2,000 tons of West Virginia Pocohontas screenings; also coal equal in heat value units to 180 tons of Youghiogheny mine run coal.

The specifications read in part as follows: "For the purpose of comparison, each party tendering must send, enclosed with tender, an analysis made by the Milton Hersey Co. Ltd., or other duly qualified analytical chemist, showing the constituent parts, and number of heat units in coal it is proposed to supply, and the coal which is selected must approximate such analysis when delivery is made at the schools. The coal when being delivered will be subject to inspection by the Chief Operating Engineer, who may have it analysed from time to time by the Milton Hersey Co. Ltd., and should such tests show results different in an appreciable degree from that sent in with the tender, the Board may cancel the contract, or make such deductions in the price as is equivalent to the reduced value of the coal."

There is nothing definite in the above specifications, as the bidder is not asked to guarantee anything for the coal supplied. He is not required to deliver coal up to a certain standard, but only "approximately" close to the analysis which is submitted with the tender. What the term "approximately" means in this case is something the contractor must depend upon the Chief Operating Engineer to define. The writer asked an official of the Board what latitude would be allowed in case the coal supplied did not test as high as the analysis submitted with the tender. The reply was that if it were a thousand B. T. U. lower he supposed there would be a deduction made from the invoice, but there was no stated variation provided for.

The bidders who offered Canadian coal enclosed their analysis as asked for, and these analyses were either ignored or the coal was listed as "not desired." The following coking steam coals were rejected as "not desired": Bellevue, Greenhill, Hillcrest, McGillivray Creek, Luscar, Mohawk and Coal Creek. All these coals have been used by the railways for years.

### Canadian Coal Rejected

Michel was guaranteed to contain not less than 13,500 British Thermal Units per pound, and therefore subject to severe penalties if inferior coal were delivered, so the Chief Engineer could not very well value it below this figure. Nothing was guaranteed for any of the American coals, and the analyses enclosed with the tenders were accepted at their full value. The unfairness of accepting these analyses and rejecting the analyses of the Canadian coals is apparent, especially when it is remembered that all American coals offered had been mined for over a year, and are much inferior to fresh mined coal.

The contracts awarded were:

3,000 tons of Pocohontas Mine Run \$12.95 per ton  
2,200 tons of Pocohontas Mine Run \$13.25 per ton  
2,000 tons of Pocohontas Mine Run \$12.50 per ton  
180 tons Youghiogheny Mine Run \$12.55 per ton  
3,000 tons of Pocohontas were bought at the base price of \$12.95. Competition for the next contract of 2,200 tons was narrowed to Pocohontas at \$13.25, which was thirty cents above the base, and Michel at \$12.45, which was fifteen cents above the base price. The Michel was guaranteed to contain not less than the number of B. T. U.'s used as a basis of comparison, yet the contract was awarded to the foreign coal at fifteen cents more per ton than the relative values as calculated by the Chief Operating Engineer.

The Commissioner of Buildings and Supplies said the Board was not prejudiced against Canadian coals, and would award the contracts to the Canadian product if their prices were lower than that of the foreign coals. In spite of this we find that practically all the business went to the other side of the line, when after eliminating most of the Canadian bids, and rating two of the others at ridiculously low values, their own figures showed that Michel was entitled to at least 2,200 tons. It might seem an error, but for the fact that this Association wrote the Commissioner on Nov. 3rd pointing out the injustice of ignoring the tender for Michel when it was admitted to be lower than its American competitor. We are informed this letter was read at a meeting of the Supply Committee before the contracts were signed, but no action was taken to reconsider the matter and our letter is still unanswered.

### Tests of Canadian Coals

All the figures given in this article so far have been quoted from the report of the Chief Operating Engineer

presented to the Public School Board when the tenders were being considered, and are grossly unfair to those firms who were offering Canadian coals, so we are appending reports of tests and analyses from reputable sources to prove our contention.

**Cadomin.**—The Milton Hersey Co., Ltd., wrote under date of Sept. 25, 1922. "We have obtained a representative sample from your Cadomin coal stock piles which analyses as follows:

B. T. U. per pound on sample as received... 13,440  
Total Combustible Matter . . . . . 84.65%

The above sample as taken, contained 1.75% of moisture (rain) and the analysis of an air dried sample is;

B. T. U. per pound on air dried sample . . . 13,640  
Total Combustible Matter . . . . . 86.40%

The School Board allowed this coal a B. T. U. content of 12,225, thereby decreasing the cash value \$1.22 per ton, which was barely enough to kill the tender.

**International.**—The Milton Hersey Co., Ltd., reported on Dec. 13th, 1922 that they had taken a representative sample of this coal from the yards of J. C. McNabb & Son, Ltd. which analysed as follows:

B. T. U. per pound on sample as received . . . 12,307  
Total Combustible Matter . . . . . 82.40%

This coal was allowed a heating value of 11,620, by the School Board, thus reducing the cash value \$0.63 per ton.

**Michel.**—This coal seems to have been the only one which was tendered on with a guaranteed B. T. U. content, so there is no means of comparing it with the American varieties which were not guaranteed, but the following reports of analyses and tests will only serve to show the bidders were within the safety zone when they guaranteed 13,500 B. T. U. This guarantee was given at the request of the Chief Operating Engineer, who intimated that special consideration would be given to guaranteed tenders, but the way the contracts were awarded proved the reverse. The Milton Hersey Co., Ltd., took representative samples out of five cars of this coal, and the average of the five analyses were:

B. T. U. per pound on sample as received . . . 13,853  
Total Combustible matter . . . . . 89.60%

In each of the cases above reported, the samples taken by a qualified chemist of the Milton Hersey Co. Ltd., and the samples reduced by the well known quartering method which is accepted by authorities as being the only proper means of securing a representative sample. The samples of Cadomin and International were taken from stock piles, and the samples of Michel were from cars. All sampling was done by the chemist without any assistance or interference from interested persons, so he alone is responsible for the accuracy of the tests.

#### *Canadian Slack Coal Also Best Value*

The above analyses are of mine run coal, and as the School Board refused to consider any tenders of Canadian slack coal we will give a few analyses of Michel and Coal Creek slack which will show the high quality of these fuels.

A car of Michel Slack was used at the McPhillips Street Pumping Station, which Mr. J. A. Blackie, City Chemist, sampled and gave the following analysis:

Sample No. 1 B. T. U. per pound . . . . . 13,515  
Sample No. 2 B. T. U. per pound . . . . . 13,789

From cars of Coal Creek slack, Mr. Blackie made the following analysis:

Sample as received B. T. U. per pound . . . 13,744

It is doubtful if the Pocohontas slack that is being delivered at the schools will equal these analyses, and the price paid is \$12.50 as compared with the tender of Michel at \$11.95 which was rejected without comment.

180 tons of Youghioghenny was bought by the Board at \$12.55 per ton, so it will be interesting to note the results of a practical steaming test conducted by the Manitoba Government at the Industrial Training School, Portage La Prairie in December last.

Each coal was tested for eight hours, and the figures here given are certified correct by Mr. L. Bickle, the engineer in charge of the tests.

#### **Youghioghenny Mine Run Coal**

Total coal fired . . . . . 1800 lbs.  
Equivalent evaporation of water per pound of coal fired, from and at 212 degrees F. . . . . 10.03 lbs.

Remarks: — Test started with running at 10.00 a.m. Fire cleared before run and at end of run. No coal put on fire at end of run. Coal was very coarse.

#### **Michel Mine Run Coal**

Total coal fired . . . . . 1800 lbs.  
Equivalent evaporation of water per pound of coal fired, from and at 212 degrees F. . . . . 11.00 lbs.

Remarks: — Test started with a running start at 10.30 a.m. Fired cleared before run and completely cleared at end of run, and 100 lbs. of fresh coal put on fire to bring it to same thickness as at the start. This 100 lbs. is included in the 1800 lbs. above mentioned. First 900 lbs. of coal was slack, next 900 lbs. Mine Run.

Certified correct.

Dec. 22, 1922.

(Signed) L. BICKLE.

From this test it is seen that Michel coal, which was half slack, proved nine per cent. more efficient than the best Youghioghenny lump, after the Michel fireman threw in 100 lbs. of coal for good measure at the end of the test.

\* \* \*

The object of writing this article is to bring to the attention of the people of Western Canada and of Canadians in general, the injustice that has been done our Canadian coals in this market. We realize there are some Canadian coals which are not capable of competing with the foreign product, but that is no reason why they should all be condemned; and in the case of the Public School Board here dealt with, the tax payers of Winnipeg are out of pocket many thousands of dollars by purchasing imported coals at higher prices than the best Canadian coals were offered. There is not a school building in Winnipeg that cannot be heated just as efficiently, and more cheaply, with our own coals than with the coals purchased. If the citizens of Winnipeg are satisfied to pay out their good money to patronize foreign industry at higher prices than the equivalent value of Canadian products, then our labor is wasted; but we do not believe this to be the case.

The province of Yunnan, which comprises the south western portion of China, is reported as rich in minerals, whose development has been retarded chiefly on account of inadequate transportation, the sea being far distant and railways almost unknown. Tin and antimony are the chief mineral products at present, but the ores of copper, iron, lead and zinc, as well as coal, are said to be abundant. The native industry at present requires little of these metals, and coal is only slowly replacing charcoal as a domestic fuel.

## RESEARCHS UNDER WAY

### *Electro Thermic Metallurgy of Zinc*

In the work on the electrothermic metallurgy of zinc being conducted at the Mississippi Valley experiment station of the United States Bureau of Mines at Rolla, Mo., experiments will be continued with the electrothermic dry distillation process. In large scale experiments with this process, difficulty has been encountered in the fact that condenser linings made from ordinary refractories break down, due to carbon deposition around particles of iron oxide contained in the refractory material. Small scale experiments will be conducted, using condensers lined with various iron free refractories to determine what materials are useful for this purpose. The physical and chemical behavior of the metals commonly associated with zinc, such as cadmium, lead and silver, during the distillation and condensation operation will be studied as well as the effect of these metals on the treatment of complex ores by the electrothermic dry distillation method, with the especial object of determining the recoveries of lead and silver possible.

### *Treatment of Zinc Retort Residues*

Large tonnages of residues from the retort distillation of zinc ores, containing much unburned coal and several per cent. of zinc as well as lead and silver, are now discarded as waste. Several methods have been proposed for treating these residues and some are in use in certain places, especially where the residues contain lead and silver. A survey will be made by the Mississippi Valley Experiment Station of the processes that have been proposed and of those now in use for the treatment of this material, and data will be collected as to the tonnages available as well as typical analyses, both of currently produced residues and of those from past operations. The information collected should be of benefit to those in the industry who are working on this problem. If the survey indicates it to be advisable, experimental work will be inaugurated by the Bureau of Mines in an effort to develop some process to recover economically the valuable contents of these residues.

### *Zinc As Roofing Material*

An investigation started by the Mississippi Valley experiment station as an inquiry into the availability of zinc as a roofing material for use on farm buildings has been broadened in scope to include a general investigation of zinc as a roofing material. The work is being directed by C. E. van Barnveld, superintendent of the Mississippi Valley station.

### *Deoxidation Or Metallization Of Calcines*

Very good results have been obtained in the deoxidation of calcines and oxidized iron ore by a tube furnace designed at the Southwest Station of the Bureau of Mines, Tucson, Arizona. A tube 3 in. in diameter by 7 ft. long was cast from Thermalloy (an iron-chrome-aluminum alloy), and was set at a slight angle from the horizontal, and operated at about 14 R. P. M. At the upper or intake end, the ore charge was fed into the tube by a worm feed to insure the exclusion of air or oxygen entering with the charge. The lower or exit end of the tube revolved in a packing joint set in the wall of the cooling bin to prevent reoxidation before cooling. Six feet of this tube forming the reaction zone was enclosed with brick to conserve the heat. This portion was externally heated to a reaction temperature of about 950 deg. C. Iron ore or calcines, plus 1-2 by weight soft bituminous coal, was passed, by continuous feed and discharge, into the tube at the rate of 20 lbs. per hour. The charge remained in the reaction zone

approximately 7 minutes, and a completely deoxidized sponge iron product was produced. Under cooperative agreement with the Tintic Milling Co., Silver City, Utah, experiments are being conducted for comparative results with Thermalloy tubes of 4, 6, 8 and 12-in. diameters, by 10-ft. long.

## CARBON BLACK FROM NATURAL GAS

Carbon black is the term generally applied to the finely divided carbon deposited when natural gas is allowed to burn in an insufficiency of air and the flame made to impinge on a metallic surface. It should not be confused with lamp-black which is made from such materials as tar and vegetable oils. Carbon black was first manufactured from artificial gas but now nearly all the world's production is made from natural gas.

During the year 1915 it was discovered that carbon black could be combined with rubber instead of the pigments formerly used to give strength and toughness to such articles as automobile tires, footwear, and other rubber goods subject to abrasion. The result was so successful that at the present time the rubber manufacturers are the largest consumers of this material. It is also used in the manufacture of printing inks, paints, paper, and many other commodities.

Nearly the whole of the world's production comes from the United States, chiefly from West Virginia and Louisiana, the amount in 1920 being 51,321,892 pounds derived from 40,598,978,000 cubic feet of natural gas. A large export trade has been built up and in 1921 the value of exports to England were valued at half a million dollars, to Japan a quarter of a million dollars, and to France nearly two hundred thousand dollars. Canada is also dependent on the United States for her requirements of approximately 2,000,000 pounds a year valued at about \$220,000.

An uncertain factor in the carbon black industry of the United States has been that of a supply of gas at low cost. There are extensive fields of natural gas available in certain sparsely settled areas in Canada, not too far removed from transportation facilities, which would possibly insure an uninterrupted supply of gas at small expense.

The question of establishing a carbon black industry in Canada appears to be well worth looking into as the demand for carbon black both at home and abroad is bound to grow. Moreover, the available surplus for export from the United States is likely to diminish rather than to increase.—Natural Resources.

The iron and steel plant of the Broken Hill Proprietary Co. at Newcastle, 60 miles north of Sydney, Australia, is still idle. In view of a renewal of operations, the company has bought a coal mine near Newcastle, and now owns an adequate supply of all raw materials. It has four blast-furnaces with a nominal daily capacity of 1500 tons, or 460,000 tons of pig-iron per annum, and seven basic open-hearth furnace with an annual capacity of 300,000 tons of steel. A recent application to the Arbitration Court for the reduction of wages that must precede the resumption of operations was refused.

Radium ore produced in the Belgian Congo now controls the world's market. It has such a high content of the precious element that it is likely the price of radium will be reduced even below its present record low level.

Investigations into the use of peat in Finland have resulted in a mechanical process much like that developed by the Joint Peat Committee in Canada, in which the sun does most of the work required.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHWESTERN ONTARIO

**RED LAKE CLAIMS.**—The total number of claims recorded with H. E. Holland, mining recorder at Kenora, as staked in the Red Lake area in the District of Patricia is one hundred and fifty seven. Of these seventeen have been allowed to lapse, so that at this writing there are one hundred and forty claims in the Red Lake district in good standing. This is quite a drop from the grand total of a thousand staked claims claimed by certain irresponsible persons and published in good faith by the daily and technical press; but exaggeration never does a district any service. After all, a hundred and forty claims in such a remote camp is not a bad showing for an autumn's exploration. The coming summer will tell the tale; either there will really be a thousand claims staked and recorded or there will be *crêpe* on the front door.

**DRYDEN.**—The sulphate pulp mill at Dryden is now making use of soapstone obtained from the deposit nearby for lining its smelting furnaces. The soapstone blocks for this purpose formerly were imported.

**WABIGOON.**—Some promising gold prospects are being opened up in the Wabigoon Lake area. Twenty-five years ago the Wabigoon and Manitou districts, south of the C. P. R., were the scene of a gold boom, which petered out in stock-jobbing, comparatively little work of exploration or mining development being done. It is quite possible that this renewal of activity, if conducted sanely and honestly, will result in the location of payable ore-bodies.

## NOVA SCOTIA

**COAL SHIPMENTS FROM LOUISBURG.**—There were no fewer than eight large ships in Louisburg harbour in one day last week waiting for coal, all making delivery at New England ports. The winter shipment of coal has kept the collieries busy this winter, and except for storms not one day has been lost. The large coal heaps at the collieries are tangible evidence of large outputs, for with all the winter shipping a considerable amount of coal has to be placed in the stock piles awaiting spring.

**D. H. MACDOUGALL ON HOLIDAY.**—D. H. MacDougall, vice-president of the British Empire Steel Corporation, has left for southern France for a well-earned rest, accompanied by Mrs. MacDougall. Few men have given such close attention to business over an extended term of years as has Mr. MacDougall. *The Canadian Mining Journal* wishes him a very pleasant vacation.

**WALTER HERD RETURNS AND A. S. MCNEILL SAILS.**—Walter Herd, Mining Engineer of the Dominion Coal Company, has just returned from Britain, where he spent several weeks getting in touch with all that is new in coal mining there. Alex. S. McNeill, General Superintendent of the Dominion Coal Company, has sailed for Britain, to remain for two months. Most of his time will be spent in the collieries of England, Scotland and Belgium. Mr. McNeill is a very capable mining man already, and it shows good judgment on the part of the Company to send him and other officials to other coal mining fields, that they may enrich their

experience with added knowledge and learn what others are doing and how they are doing it. Governments send out representatives to collect new ideas and find what the rest of the world is doing, so why not large corporations? Nova Scotia coal fields combine many of the features found in foreign coal fields, and it is money well invested to have officials responsible for the Canadian mines become personally acquainted with problems and methods in other fields. Under the superintendency of Mr. McNeill the outputs of the Cape Breton collieries has made large gains, and it is not unsafe to predict that at a date not far distant 20,000 tons daily output may be reached.

**THAT LABRADOR GOLD!**—There are more smiles than serious faces when the reputed new placer fields of Labrador are discussed in Sydney. Last week there was a telegraphed inquiry to the Board of Trade to ask whether adequate shipping would be available to accommodate the gold seekers in the spring. After the laughter had subsided, the Board of Trade decided that they could find ships for all comers.

**THE REDS AGAIN.**—J. B. McLachlan and his group of radical enthusiasts at Sydney will not be downed by President John L. Lewis of the U. M. W. A. He has sent a letter, signed on behalf of District 26, in which he defends the principles of the Red International, and states that he looks for redress from the incoming headquarters board of the U. M. W. A.

**PICTOU COAL PRODUCTION.**—The mainland collieries of Nova Scotia, as well as those of Cape Breton, are thriving. During 1922 the Acadia Coal Company of New Glasgow shipped 365,723 tons, as compared with 320,064 tons in 1921. Assistant General Manager J. J. McDougall reports that the collieries are in first-rate shape and will soon be back to pre-war production if conditions for selling remain good.

**SHORTAGE OF MINERS.**—There still remains a decided shortage of skilled miners in the collieries of the province. It is possible to fill the need by means of training new miners, but that is slow work at best and meantime the province, as well as the companies, is wasting an opportunity for further advance in its coal trade.

## COAL AND METAL MINES IN CANADA

The Mines Branch, Ottawa, now have ready for distribution the revised lists of *Metal Mines in Canada* and *Coal Mines in Canada*. These lists are quite formidable in size, and in the case of the coal mines most of those listed are marked as active. The list of metal mines contains many that are moribund, and where possible these are noted as such. As the metal mines are not under such strict government supervision as coal mines and as they are likewise more widespread in distribution and in more remote parts of the Dominion, reliable and recent information about them is harder to obtain. The Mines Branch asks for co-operation from the mining public in keeping these lists up-to-date. Information is given as to the name of the operating company, address, name of mine, location and address of mine and the manager.

## BRITISH COLUMBIA

**CANADA COPPER HOLDINGS.** The report that the Granby Consolidated Mining & Smelting Co. contemplates the absorption and the operation of the mine and plant of the Canada Copper Co., Copper Mountain, directs attention to the latter properties, which are situated close to Princeton and upon which much development has been done. Not only has considerable diamond drilling and other exploratory work been carried out, with the result that a large body of low-grade copper ore has been proven, but a concentrator has been installed at Allenby, some miles distant, and a railway constructed from the same to the mines at heavy expense. It was stated at the time the mill was first ready for use that a contract had been entered into with the Consolidated Mining & Smelting Co. of Canada for the shipment of the concentrates to the Trail Smelter and it is a fact that power was to be derived from the West Kootenay Power & Light Co., of Bonnington Falls near Nelson, the extension of the wires for this purpose having been practically completed. With plans rapidly nearing fruition, the project of actual mining and milling the ores of Copper Mountain came to a sudden halt. The low price of copper at the time was generally believed to be the explanation of this and lately there has been speculation locally regarding the future of the enterprise, having in mind the improvement of the copper market.

Certain British Columbia mining men claim that the preliminary work at Copper Mountain proved 10,000,000 tons of ore, with another 2,000,000 tons of "probable" ore. The values are said to average 35 cents per ton in gold and silver and thirty-four pounds of copper per ton. As to the mill, its capacity is placed at 2,000 tons a day, and a trial run in 1920 was satisfactory except in one particular. The ore proved to be tougher than expected and it was found that heavier crushers and rolls would be necessary. Since that time the plant has been idle. The cost of the railway, which runs up the Similkameen River and gives the mine connection with the Kettle Valley Railway, is estimated to have been \$2,000,000, having proved one of the heaviest pieces of construction ever put through in a country with a reputation for costly railway work. To put this railway in shape for use doubtless would mean a substantial outlay as there have been mud and rock slides during the period of idleness.

**MINE ASSESSMENT.**—What is the proper allowance to be made for depletion in the assessment of a mining property for purposes of taxation? What is a just and equitable method of arriving at a basis upon which to figure whatever rate of taxation may be adopted?

As it is at present in British Columbia the Minister of Finance is given the power of the final adjudication. The Surveyor of Taxes proceeds with the work of assessing and in due course the companies, or the operators, affected receive notice of the results of his computations. If they are not satisfied there is available the recourse of an appeal to the Finance Minister.

Mining men, or at least many of them, do not think that this is a commendable system. They criticise it from various angles but, perhaps, the chief objection is that there seems to be no fixed and generally understood regulations under which the taxation department can function in estimating such allowances as that made for the depletion of a mine. Consequently operators say they are unable to estimate and make provision for their provincial taxes from year to year. Such a condition

is not conducive to stability. It has the tendency, it is stated, to discourage rather than to stimulate the interest of outside capital.

The taxation department has declared its wish to deal fairly with the industry. It asks only that the producing mines pay their proper proportion of the financial burdens of the country, having regard for what is collected from other forms of industry and from citizens generally. As the extraction of minerals means the exploitation of the country's natural resources for the gain of one or more individuals, and as what is taken is irretrievably gone, it is maintained that the State is justified in exacting an equitable tax on production earnings. While standing thus on a principle universally recognized, the department appreciates that capital must be encouraged to invest, that the plea for stability or reliability in taxation methods in order that operators may be inconvenienced as little as possible is well founded, and that, if the present practice is as faulty as is alleged—and this by no means is wholly admitted,—it would be of advantage to have some changes introduced.

All these matters, it is understood, were informally discussed at a recent meeting between officials of the Taxation Department and of the Mine Owners Association of British Columbia. The owners were represented by Messrs. Clapp and Young, of the Granby Consolidated Mining & Smelting Co.; Mr. Bingay, of the Silversmith Mines Ltd.; and Mr. Mortimer-Lamb, secretary of the Association. The conference was called on the invitation of the Department, not with the idea of arriving at definite conclusions but with a view to receiving suggestions at the hands of those actively engaged in mining in the Province. From these conferences it is thought that possibly some system may be evolved that in its application will be more equitable than the present method. The desire, it is stated, is to make improvements if any are found practicable.

Capital is entitled to expect that it be permitted a fair rate of interest and that, when the ore reserves of the mine in which it is invested are exhausted, the original outlay, together with adequate interest, shall have been returned. Given a knowledge of the total investment and accurate information as to the reserves and the returns from the same, and the figuring of a proper allowance for depletion is but a matter of rudimentary mathematics. This ideal condition, however, is found in few, if any, of the mines of this Province. In what class are the mines of the Slocan, for instance, to be put? Some of these have been abandoned by the owning companies, leased with or without option to purchase to enterprising miners, a rich stringer or two worked and several carloads of very high-grade ore shipped to the smelter. How is an allowance for depletion to be arrived at in such cases? And there are many properties with regard to whose ore reserves little is known. As a matter of fact almost every one of the producing mines of the Province seems to present an entirely distinct and separate problem for the assessed and the tax collector. To place one group in one class and another differently and apply a different set of regulations to each appears to offer insuperable difficulties.

Notwithstanding the complexity of the problem, however, there is much to be thankful for at present. When both sides are found anxious and willing to work together, appreciating that each has troubles and that each is anxious to effect an equitable adjustment, there is every hope that a satisfactory settlement will be reached. It is stated that there now is a very clear un-

understanding between the Taxation Department and the Mines Owners, that the latter have presented a concrete proposition that will be given consideration, and that there is no doubt that the policy is to assist in every way towards the building up of the mining industry of the Province.

**TRAIL ORE RECEIPTS.**—Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co., for the month of January totaled 35,978 tons, as compared with 36,943 tons for the same month last year. Of the former amount 31,690 tons were from the company properties, 4,288 tons being custom ore.

Receipts for the last ten days of January were 10,505 tons, made up as follows:

|                                  |          |
|----------------------------------|----------|
| Alamo, Alamo . . . . .           | 58 tons  |
| Black Rock, Northport . . . . .  | 83 "     |
| Company Mines . . . . .          | 9,231 "  |
| Henderson Gp, Smithers . . . . . | 48 "     |
| Knob Hill, Republic Wn . . . . . | 262 "    |
| Krao, Ainsworth . . . . .        | 23 "     |
| Lone Pine, Republic Wn . . . . . | 172 "    |
| Paradise, Invermere . . . . .    | 77 "     |
| Quilp, Republic Wn . . . . .     | 115 "    |
| Silversmith, Sandon . . . . .    | 150 "    |
| Steel Gp, Brisco . . . . .       | 31 "     |
|                                  | <hr/>    |
|                                  | 10,505 " |

**PIONEER PASSES.**—Thomas Mills, a veteran coal operator and prospector, died at Nanaimo on January 31st, aged 68 years. He managed several of the coal mines of Vancouver Island during their early years.

**MINE EXPLOSION.**—Preliminary investigations have failed to reveal the cause of the disastrous explosion that wrecked No. 4 mine, Cumberland, Vancouver Island, last week. The bodies of all the 33 victims have been recovered.

## CLEANING FILTER LEAVES

A useful method of cleaning filter leaves is described by T. B. Stevens in the *Journal of the Chemical, Metallurgical and Mining Society of South Africa* for November last. It is as follows:

The usual method of removing the lime incrustation from filter leaves is by circulating weak hydrochloric acid through them. This is satisfactory as regards renewing the porosity of the cloths, but it is costly for acid, especially where the acid has to be transported any distance; it has also other minor disadvantages. At Kalgoorlie it was found that with certain modifications the hydrochloric acid can be replaced with the less expensive sulphuric acid. The leaves are first removed from the filter vat and freed from adhering slime and any loose incrustations by washing and brushing in the usual manner. If the cloth is very hard a wire brush such as is used by fettlers for cleaning castings is a good tool to use, as it opens up the cloth. The leaves are next immersed in a bath containing a 2% solution of sulphuric acid, and allowed to soak in it for one hour. By this treatment all of the lime salts are converted into calcium sulphate and a considerable portion of it will be loosened and will fall away from the cloth. Some, however, will still remain in the fibre of the cloth, and this is removed by transferring the leaves to another vat and circulating fresh water through them for two or three

days. At 18° C., one part of  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  will dissolve in 386 parts of water, or in other words, one hundred gallons of water will dissolve nearly three pounds of calcium sulphate. The ease with which it will dissolve and the cloth softened has to be seen to be thoroughly appreciated.

The plant required for this treatment is of the most simple kind. The acid bath, if built of sound timber, three inches thick, will last for years, and one capable of accommodating six leaves is large enough for any sized filter, as the time of contact required is so short. The water vat may be of any size, either round or rectangular, and needs to be fitted with a manifold pipe on one side to which the leaves are attached. In some instances, I have forced the water through the frames, and in others I have used a small plunger pump to suck it through them. The choice of method is dependent on local conditions. The water after being used for this purpose can be utilised either to make up the mill circuit, or for the disposal of residue. Where water is scarce the same water may be circulated through the leaves until at least half saturated with calcium sulphate. The solubility of calcium sulphate may also be increased by the addition of common salt.

The softening process has been found to be just as efficient as when hydrochloric acid is used, for when the leaves are returned to the filter they will have the same duty. The cost of cleaning is very much less, for at Kalgoorlie, whilst the theoretical cost of dissolving one pound of calcium oxide with hydrochloric acid is fourteen pence, the same work can be done with sulphuric acid for four pence. The sulphuric acid treatment has also the advantage that no acid proof apparatus is required to circulate the acid. Another minor advantage is that the corrosion of the pipe-work frames is also not so great as when hydrochloric acid is used.

The greensand marl that occurs so extensively in New Jersey is not at present being used as a source of potash, though formerly it was so used. Investigations conducted by the United States Geological Survey, and described fully in Bulletin 727, recently issued, show that 257,000,000 tons of potash is potentially available by quarrying from these beds. Attempts to make use of the glauconite, which is the silicate containing the potash of the greensand, are constantly in progress, but none have been commercially successful so far.

A British company, Mozambique Oil and Mineral Concessions, Ltd., with mineral concessions in Portuguese East Africa is stated to have determined by prospecting extensive beds of auriferous gravel on the Nahavara and Nanirue rivers. A dredge has been ordered and is expected to be in operation before autumn. It is expected that this will be the first of a fleet of dredges.

Data collected by the United States Geological Survey show that over the country as a whole 40 per cent. more bituminous coal than usual was distributed by retail dealers during November and December last. In the territory where anthracite is ordinarily the domestic fuel, the increase in the delivery of bituminous coal was 35 per cent.

## Let Hercules Oils Increase Your Profits

Steam-distilled pine oil is conceded to be the best flotation frother known. Moreover, it is the cheapest flotation reagent in the long run because it recovers the greatest amount of concentrates per ton of ore.

This very fact has found favor for Hercules Pine Oil with many flotation operators and engineers.

Hercules Pine Oils are produced under strict chemical control. The grade of oil which best meets your needs having been determined, we can supply that grade in absolutely uniform shipments. We invite correspondence and offer the services of our technical staff in helping you solve your flotation problems.

## A Basis of Confidence

This Bank's strong financial position assures ample protection to those making it a depository of business funds. The paid-up capital and reserve, and assets of over \$126,000,000 constitute a sound basis of confidence.

Established nearly fifty years ago the Imperial Bank has expanded side by side with the development of Canada's mineral resources

With over 200 branches covering the Dominion and strong affiliations abroad, this Bank is enabled to fulfill every requirement of modern banking, domestic or international!

## TORONTO MINING TANKS

ONTARIO WIND ENGINE & PUMP CO. LIMITED

The last eight months has seen an unprecedented output of TORONTO Tanks. In fact, the demand for TORONTO Quality Wooden Tanks has been the greatest in our experience and proves that these tanks are leaders.

TORONTO Mining Tanks are built from well seasoned air dried stocks in either B. C. Fir, Redwood, Cypress or Pine. Built in any size or shape to meet local conditions.

Our Engineering Department will gladly furnish full information and prices — without any obligation of course. Write today for your copy of illustrated folder on TORONTO Tanks.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.      | Value.      | Year.      | Value.       |
|------------|-------------|------------|--------------|
| 1891 ..... | \$4,705,672 | 1906 ..... | \$22,388,383 |
| 1896 ..... | 5,235,003   | 1911 ..... | 41,976,797   |
| 1901 ..... | 11,831,086  | 1916 ..... | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

**THOS. W. GIBSON,**  
Deputy Minister of Mines,  
TORONTO, CANADA.

## The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, \$76,177,403; Lode Gold, \$105,557,977; Silver, \$55,259,485; Lead, \$48,330,575; Copper, \$166,393,488; Zinc, \$21,848,531; Coal and Coke, \$225,409,505; Building Stone, Brick Cement, etc., \$34,072,016; Miscellaneous Minerals, \$1,210,639; Making its mineral production to the end of 1920 show an

**Aggregate Value of \$734,259,619**

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for the year 1916, \$42,290,462; for the year 1917, \$37,010,392; for the year 1918, \$41,782,474; for the year 1919, \$33,290,313; 1920, \$35,543,084; 1921, \$28,066,641.

**Production During last ten years, \$336,562,897**

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

**VICTORIA, British Columbia.**  
**THE HON. THE MINISTER OF MINES.**

**FOR  
YOUR CONVENIENCE  
IN DEALING WITH  
MATTERS ELECTRICAL**

A Canadian manual of current information concerning matters electrical in the Dominion will be published a few weeks hence under the title of

**THE  
ELECTRICAL DIRECTORY  
OF  
CANADA**

**Where To Buy Anything Electrical** — a Buyers' Guide of 350 pages, listing 1,200 classified electrical items, covering almost every item of electrical apparatus, appliance or supplies in current use.

**The Electric Power In Each Locality** of the Dominion — The current voltage company or commission for 1,050 localities. This comprises almost every locality in the Dominion, having a population of 300 or upwards.

**The Principal Officers, Capitalization and major plant equipment** for each company producing electric power. Edited specifically for Canadians from the Canadian view point.

**The Product Of Many Months Of Intensive Effort** by a qualified staff under technical direction.

**Information obtained From Original Sources** — through an extensive correspondence with responsible officials in all quarters of the electrical industry.

PRICE \$5.00

## *USE HISCO BALLS*

"If quality counts use 'Hisco' Products" *Hisco Balls* are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to

Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.

Sizes 3, 4, 5 and 6 inch carried in stock.  
Special sizes from 6 inch up made to order.

## -:- EDITORIAL -:-

*The [Canadian Mining] Institute, while fully believing in the natural mineral wealth of Canada, can yet afford to act as a sort of "safety valve" to guard against the evil effects of "wild cat schemes" and the exaggerated reports that too often back them up. — G. E. Drummond — 1898*

### WANTED — A POLICY OF ACTION

Commendable energy and initiative has been displayed once more by the Western members of the Canadian Institute of Mining and Metallurgy in their contributions on Institute Policy in the current issue of the *Monthly Bulletin*. These Western members are at present the "livest" section of the Institute, they are well organized, and they have a definite and stated policy whose adoption they consider will be in the best interests of the Institute as a whole. We consider that the adoption of their policy as stated would be detrimental to the Institute as a whole, though it might well serve the immediate objects of these Western members. As the arguments pro and con have tended principally to veil the main points at issue rather than to illuminate them, we shall set down here what we consider to be the principles involved.

All are agreed that at present the Institute suffers from the non-application on its behalf of the talents and energy of its members. There is plenty of both talent and energy available, but for some reason Institute activities fail to receive their just share of them. Our Secretary says, in effect, "Open wide the doors to men of business and executive ability who are not now members, and we shall then have the stimulus to action we now lack." The Western members reply, "We have already too many uninterested outsiders in our midst. Give us a homogeneous membership and our problem is solved."

Both these ideas are, we hold, merely partial and both miss the real point. Our membership is by no means perfect, and never will be; but it includes the whole of the mining engineers of Canada and a host of men of first-rate ability who are not engineers, but who are actively interested in mining. If the mining engineers wish to promote the interests of their profession, they are there, in full assembly, to do it. If the Institute wishes to benefit by the co-operation of business executives and specialists in finance, it can be had for the asking from numbers of its members. What the Institute lacks at present is neither men nor adequate objects on which to expend its energies. If we formulate such objects and make provision for their accomplishment, our Institute will take up a new lease of life. This is the vital point that either has escaped

the notice of those taking part in recent discussions or has not been given the prominence due to such an essential consideration.

The Western members will say that they have already set forth an object well worthy of the Institute's attention; by making the Institute more nearly a purely professional body, we shall provide automatically for the productive activity all of us so much desire. We question the soundness of this conclusion; it is an assumption. What is our warrant for assuming that because all the members of the Institute are responsible members or adherents of the profession, they will be thus stimulated to creative effort? Furthermore, the avowed objects will tend to serve the professional engineer rather than the industry. The origin of this one-sided views can be readily understood by examining the names of those who signed the "Letter to Members" in the last *Monthly Bulletin*. Teachers and geologists comprise the larger part of the list, and the great world of affairs is almost without representation. These members and many others who agree, or partially agree, with them are rightly impressed with the potential power and influence of a professional organization of mining engineers; but we hold that such an organization is bound to act on behalf of its members rather than on behalf of the mining industry as a whole, whenever the interests of the profession and of the industry fail to coincide.

The united effort of the Western members of the Institute, by virtue of its very fact of concerted action as well as its laudable objects, has made an impression upon the members in general that is quite out of relation to the numbers supporting the move. There is danger that their arguments, so convincing on first reading, will carry the day at the annual meeting in March. The energy and initiative of the Western members and even their present objects can, we believe, be turned to good account in ways we have suggested previously in these pages. Meantime we urge, once more, that members at large examine the other side of the case as well, in preparation for the meeting, with the object of preserving in the by-laws an idea that was fundamental in the minds of those who founded the Institute.

### THE PARLIAMENTARY SESSION AND MINING

The present session of the Federal parliament promises to be more fruitful of practical measures affecting the mining industry than the last, which was decidedly barren of such results. Already a number of minor measures have been introduced. The vote for exploration and surveys in the Northwest Territories has been increased substantially. An appropriation for \$600,000 has been made for "migration within the Empire", in conjunction with the Imperial government under the Empire Settlement Act. Our archaic patent law is to be amended to bring it in line with modern international patent practice.

These items are important enough to warrant the close attention of Parliament, yet none of them touches the mining industry vitally. If our present Parliament has stiffened its spine since the close of its first session (and there is evidence that such is the case), then we may hope for some genuine steps in the progress of mining affairs, so far as they are affected by Federal administration. Chief among the questions up for settlement is the ownership of natural resources in the prairie provinces. Until the provincial departments of mines are fully responsible for the mineral resources of their respective provinces they cannot tackle their various problems with the vim and the assurance that alone will result in real progress. It is up to the trustees of our national resources in Ottawa to speed up the settlement of this question with every resource at their command.

The conference on industrial research called by the Canadian Manufacturers Association is now sitting in Ottawa. We do not doubt that this conference will recommend the establishment of a central research organization of national scope. This will involve action by our national administrative body, and we hope there will be enough vigour available to overcome the ineptitude lately displayed by our revered Senate and the procrastination that marked the last session of parliament. This national question must be handled in a truly national way.

### QUEBEC'S NEW GOLD AREA

There is a winter "rush" in progress at present to the new gold area in northwestern Quebec, and in the spring there will be an influx of much larger dimensions. As the active interest of those actually in the field and those who intend to go there, and the more remote interest of thousands who are following the course of events, is well founded, it will be worth while to review here the present status of the embryo gold camp, as well as to forecast the probable course of events.

The interest in Rouyn and Boischatel townships has a sound and substantial foundation. The geological

association of rocks that has proved to be productive of gold throughout northern Ontario occurs in these townships, and beyond, and gold in erratic shoots or in quantities too small to be worked was found years ago in adjoining areas. The stated opinion of geologists that the area is favourable for the occurrence of workable veins has been put to the test by prospectors, and two deposits, the Hamel and the Thomson-Chadbourne, both in the northwest quarter of Rouyn township, are now being tested further by stripping and diamond-drilling. Both these deposits show so far the rare quality that makes a mine possible — consistent values that persist through a width and over a length sufficient to warrant the expense of making a mine and building a mill. Both are promising, but not yet proved. Only the stripping, diamond-drilling and shaft-sinking of the coming summer can determine this point, and it may even require a considerably extended period. Mr. Hamel and associates have let a contract for diamond-drilling on the Cockeram claims, and the Thomson-Chadbourne syndicate have now on the road to their Powell claim a 50-horsepower boiler and a small compressor to aid in sinking a prospect shaft.

Apart from these two prospective ore-shoots, there is little or no definite knowledge of payable gold deposits in the field. These two discoveries, however, warrant a very thorough search for more of their kind, and any activity conducive to such a search is advisable. The townships of Rouyn and Boischatel are now covered almost completely by claims, staked mostly on the snow. There are about 200 men now in the area, and a stream of humanity moves to and fro every day on the winter road from Dane, on the Temiskaming and Northern Ontario Railway, 40 miles to the west. The nature of the mining laws not only of Quebec but of the other provinces makes it necessary thus to preëempt land. It is like the proverbial "pig in a poke"; but there is no other way at all of getting a porker in this case.

The winter staking will, no doubt, exhibit all the usual degrees of ingenuity and stupidity. The areal geological map made by Dr. M. E. Wilson and issued by the Geological Survey in 1913 is the only published map of the district. Though it lacks detail, as all areal maps must, still it has proved very useful. As shown in the reproduction published in these pages on November 17th last, the northern part of Boischatel township is a blank, as it was not examined. The map and report of Dr. H. C. Cooke giving the results of last summer's surveys have not yet been published; but fortunately a good deal of valuable information has been made available through the personal contact of geologist and prospector. The prospector who knows his job has searched out, first on the map and then on the ground, the conjunction of geological conditions known to be favourable to the occurrence of gold; that is, he has examined the rocky hill-sides that are bare in

spite of the blanket of snow that covers the level ground, and has put up his stakes where he finds side by side outcrops of porphyry or granite and Temiskaming sediments. If he is a real prospector, this will be only a preliminary to a thorough search on his claims next summer. Winter staking is illogical and wasteful of effort, but it has the virtue that it tends to promote the intensive prospecting without which few mineral deposits are to be found in the Laurentian plateau.

There is sure to be intense activity in the Rouyn-Boischatel field next summer. Much can be done by public servants to aid the prospectors who will there strive to add new units to our mineral industry. The Geological Survey at Ottawa will have ready by the spring, no doubt, Dr. Cooke's map and report, than which there can be no more practical aid. The Federal and Provincial departments will doubtless provide for further geological mapping of the field and the prompt publication of maps and reports. The recording of claims must now be done at the parliament buildings in Quebec. It is possible that the volume of recording in the new district will warrant the establishing of a branch recording office in the field. It was the rush to Cobalt that marked the first step in the de-centralising of the recording of claims in Ontario. Such a step would be a boon to prospectors in northern Quebec. Then fire-rangers must be provided in sufficient numbers to prevent conflagrations. All possible publicity as to developments must be given, as an aid to genuine investors and a deterrent of the wild and dishonest stock flotations that are sure to be attempted. Above all, provision must be made for ensuring the prevalent regard of law and order that have marked all recent mining rushes in Canada, a characteristic of which all Canadians can justly be proud.

#### THAT LABRADOR GOLD!

It is a painful contrast to turn from the genuine development in northwestern Quebec to the ridiculous furore about Labrador. One cannot say that the excitement is *in* Labrador, for there is not a soul in that ice-bound coast at present to keep an eye on the tons of gold that are alleged to be there. The excitement is based upon the unauthenticated statement of a disappointed speculator in Labrador pulpwood areas, who has returned to Montreal and started the ball rolling by means of skilful, though obvious, newspaper propaganda. The newspapers have been tools in his hands.

There is no evidence that the so-called placer diggings will ever produce an ounce of gold. The promoters of the Labrador scheme are taking advantage of the present public interest in gold mining to fill their own pockets, whatever the outcome in far-off Labrador.

The Newfoundland government has made itself a party to this scheme, for it has as yet made no public statement of the facts as they are known to the initiate, and its silence is tacit encouragement to those who are trusting their money to the Montreal promoters. It behooves the responsible members of that government to clear their skirts while yet there is time.

#### EDITORIAL NOTES

Widespread sympathy will be felt not only for the relatives of the victims of the mine explosion last week in colliery number four, Cumberland, British Columbia but also for the mine officials whose care and foresight have been frustrated by the unseen forces of nature. The responsibility for human life of a colliery manager and his staff is equalled in few positions in the mining profession or in any other part of modern industry. Acknowledgment and honour are due the men who undertake this responsibility and who, in the vast majority of cases, fulfil it successfully, but at the price of untiring watchfulness and care.

The Imperial Oil Company has demonstrated what can be done to promote not only harmony but good fellowship and a spirit of hearty co-operation between employer and employee. They have adopted for the direction and control of their relations with their employees from coast to coast the Joint Industrial Council plan, devised in England and now giving such splendid and widespread satisfaction there. This scheme not only gives all workmen a fair representation at a joint council, but likewise puts upon all workmen through their elected representatives, the burden of decision and the responsibility of carrying their decisions into effect. The plan is thoroughly in accord with British traditions and with democratic principles, and has a most beneficial effect in educating both employer and employee. Its present success in Canada as reported in the February issue of the *Imperial Oil Review* leads one to hope that it will be more generally adopted.

#### THE ANCHORITE

Give me the morning in winter when snow lies  
Light as a mist on the crust underneath;  
Free as a raucous-voiced wandering crow flies,  
Leave me to wander o'er hill and o'er heath.

Give me the evening, calm, wondrously jewelled,  
Winter's deft wizardry decking the land;  
Give me a cabin, well chinked and well fuelled,  
Books, — and what more can a mortal demand?

Someone responds, in a manner satiric,

Plainly desiring to give me a rub,  
That, in evolving this passionate lyric,  
Somehow I've left out all mention of grub!

J. C. M.

in the mine as the 4,100-foot level, it being about that distance vertically below the outcroppings on the Fairview mineral claim, from which the levels in the mine are numbered, the outcrop being zero. This main haulage-adit is about 4,900 feet long, 13 feet wide by 9 feet high, and is connected with the mine-workings on the 2,700-foot level by an incline rock-raise on a 65° slope, 1,488 feet high. This raise was finished in November last, and everything is in readiness for haulage operations by this route, which supplants the incline tramway from the 2,700-foot level to the ore-bunkers at Britannia Beach.

The new mill is designed so that the ore from the mine, broken on the crusher level in the mine to a 2½-inch ring size, will be hauled in cars of 20 tons capacity through the main haulage-adit and delivered into ore-bins on the top storey of the mill, where five bins, each having a capacity of 500 tons, will receive the broken ore. From these bins the ore passes through feeders to a collecting-conveyor equipped with a magnet and on to two Hummer screens from which the undersize, ¼ inch or less, is carried to the lower storey of the mill, and by a cross-conveyor to a belt-conveyor equipped with a tripper into six ore-bins, each having a capacity of 750 tons. The oversize goes to a set of 72-inch rolls; the material under ¼ inch is removed by Hummer screens and sent to the bins, and the oversize goes through 54-inch rolls and is returned to the screens.

From the bins the ore is carried by belt-conveyors to a weightometer, and from it into an automatic sampler. From the sampler the ore passes to three Hummer screens, from which the undersize passes into Dorr classifiers, of which there are eighteen. The oversize from the Hummer screens passes into six Hancock jigs, from which the concentrates are dis-

charged into a dewaterer, from there to an automatic sampler, which discharges the remainder to a belt-conveyor connecting with a weightometer, from which the concentrates are carried to bins ready for shipment. Middlings are returned to the circuit to pass through the jigs once more, and the tailing to the Dorr classifiers with the undersize from the screens.

The sands from the Dorr Classifiers are discharged into eighteen tube-mills, each 7 by 10 feet, and from these are returned to the Dorr classifiers, the overflow from which, together with the overflow from the dewaterer following the jigs, combined as well with the overflow from the jigs, is conveyed to flotation cells. The flotation concentrates are conveyed to an automatic sampler, from that into three Dorr thickeners; thence into two vacuum-filters, which discharge to a belt-conveyor connecting with a weightometer and finally are conveyed to the flotation concentrates bin ready for shipment. The middlings from the flotation-cells are conveyed to an air-lift and returned to the cells for re-treatment. The tailings from the cells are conveyed to an automatic sampler, sampled, and discharged to waste-dump.

The bunkers on the shipping-wharf that have been used in the past to load concentrates into vessels have been abandoned, and in their place the jig and flotation concentrate bins in the mill will be used for storage-bins, which will be connected with the hold of a vessel at the wharf by a belt-conveyor about 2,000 feet long. This arrangement removes all danger from fire in the wharf bunkers, which has always been a source of anxiety.

The officers and staff of the Britannia Mining and Smelting Co., have earned the esteem of the Canadian mining fraternity, and the *Canadian Mining Journal* offers hearty congratulations for the spirit as well as the technical skill they have displayed.

## Experimenting with the "Human Mechanics" of Industry

LABOR REPRESENTATION IN THE COLORADO FUEL AND IRON COMPANY

By JEROME DAVIS  
In "Industrial Management"

Imagine yourself being conducted through a huge industrial concern which covers over half a million acres and includes the best coal and steel properties in the state of Colorado. Miles upon miles of huge steel furnaces tower aloft belching forth clouds of dense black smoke. Enter one of the dingy buildings flanked by long lines of railroad cars and you see revolving wheels, pounding sledge hammers, rapidly moving cranes, — in short, all the mystifying details of mammoth machinery in action.

Here is a machine which takes hot steel and draws it out into fine wire one fourteen-thousandth of an inch in diameter. There is a huge automatic mechanism which almost at the speed of a machine gun keeps spitting nail after nail, four hundred a minute. The instruments are almost uncanny in their human-like qualities, acting in a far more marvellous way than does the magician who entertains and mystifies us in the darkness of a theatre. For example, they will take a few strands of wire fed into metal hands on steel rollers and — presto! in another half second many kinds of barbed wire fencing appear ready to make barricades against wandering tramps and rest-

less cattle. Or again, watch a white-hot ingot two feet in diameter as it is suddenly seized by mammoth steel jaws, flattened, lengthened and passed on over rapidly moving iron rollers until it finally appears as the last word in steel rail construction. Every eight hours this machine turns out over four hundred tons of steel rails. Or come inside a huge pitcher-like building, a Bessemer furnace, the home of liquid steel. After the metal has been heated to the proper temperature, a stopper is removed, and little rivers of molten metal dash down in silver rapids. The glowing mass soon separates into two streams. The pure metal, which will harden into the finest steel, flows out under a metal dam; while the slag and impurities pour over the top into another reservoir.

One's admiration for the directing genius of the company increases; we should give due credit to the inventors and directors of such mechanisms, so fearfully and wonderfully made. Yet while fascinated by these processes, one becomes aware of human beings everywhere in the background who, one suspects, are largely responsible for the results obtained from the machines. We learn with amazement that there are five thousand of them in the Minnequa Steel

Plant alone. The handling of these men, their organization and direction, constitute the "human mechanics" of the business. The conditions surrounding the human factor determine to a large extent whether the corporation has a soul or is a mere machine for the production of goods, regardless of the welfare of human beings.

Of this human element, at this plant, Americans constitute a majority, while forty-five per cent. are Mexicans; the two groups together comprise ninety-seven per cent. of the working force. All of them have their life problems, their ambitions, their misfortunes, their longings, their homes — and a large number have their children. How does the industrial machine treat these thousands of toilers?

The records in the dispensary show that not more than twenty-five are injured a day and that most of these receive only minor casualties, such, for instance, as a speck in the eye. The machine is rather cruel to its masters but the record compares favorably with the best that our present industrial mechanism has yet been able to devise. Human workers are too careless and foolhardy to abolish accidents completely. The company has provided a splendid hospital and dispensary to care for the men and their relatives. In addition to the accident cases there average half a hundred others who bring their tales of affliction to the dispensary each day; ranging from colds to infectious diseases. Besides accepting medicines for themselves, they take away more for their friends. In matters of accident and disease, the human factor is admirably provided for.

The United States Steel Corporation has replied to her critics by continuing the twelve-hour day and the seven-day week. Other prominent corporations have attempted to settle the vexed question through the open shop drive. Among constructive solutions which do not attempt to deal directly with the labor unions, the plan of the Colorado Fuel and Iron Company merits attention. With the cooperation of company officials the writer visited their steel plant located at Pueblo, the concern which we have been describing. Later he took an automobile tour with the president's industrial representative through their mining properties. It was in this company that a strike resulted in the so-called Ludlow disaster of 1913 in which state troops and workers engaged in battle with heavy casualties, together with the burning of the strikers' tent colony. Out on the bare plains, far from any habitation, the United Mine Workers have erected an impressive monument to commemorate the men, women, and children who here lost their lives. These tragic incidents helped the company to inaugurate a plan of joint representation of employees and management which has been popularly called the "Rockefeller plan." It was adopted in 1915 by vote of the employees of the mines, and in 1916 by the employees of the steel works.

Briefly, it takes cognizance of the human mechanics of industry; recognizes the four parties to industry — labor, capital, management, and the community — and admits that relationships within the company should provide for the rights of each. In other words the plan tries to apply the a-b-c principles of industrial relationship: — contact, representation and cooperation.

The main points of the mechanism are quite simple.

Each division of steel plant or mine elects annually, by secret ballot, one representative for every one hundred and fifty employees. Those elected meet three times a year in district conferences with an equal number of men appointed by the president of the company, and once a year in a general conference with representatives from all the plants. Besides this each district has four committees composed of an equal number of the representatives of employees and the management. These are: the committee on cooperation, conciliation and wages; the committee on safety and accidents; the committee on sanitation, health and housing; and the committee on recreation and education.

The plan has now been in operation long enough for at least a preliminary estimate of its value. After touring from mine to mine, talking freely (and alone) with the miners, their representatives, and with strikers who are fighting the company, the writer believes the following to be a fair appraisal of the results achieved.

The elections are fairly held. In some instances there were complaints of company control, but the overwhelming majority seemed satisfied. The general method was to call a mass meeting to select the nominees and later, at the same meeting or on another day, to hold the election. Of course, each mine had its own custom about the precise plan of procedure. Many admitted that the chief problem was to interest a sufficient number of workers to vote, just as is often the case in the outside world of politics. Some voiced the belief that more should be done to acquaint the men with the facts about the elections and the necessity for their participation. Yet much has been done. During six years, one hundred and ninety persons have been elected to serve as employees' representatives and of this number one hundred and eleven are still in the company's employ. The workers do not give the men long terms, since one hundred and twenty served for one year only. They are of almost every nationality, average just over thirty-eight years of age, and have been with the concern for an average of twelve years.

Since its inauguration the system has provided an open channel for grievances. In our national government dissatisfied voters have their opportunity on election day. Similarly, under the representation plan a dissatisfied worker can approach his representative and demand satisfaction. The representative first takes up a complaint with the foreman and superintendent; then, if necessary, with the joint committee; after which it can be appealed to the president's industrial representative; and finally to the president himself.

During the first six months of 1922, there were 49 requests accepted (that is, settled in favor of the complainant) by the mine superintendents, while 22 were rejected; the president's industrial representative accepted 50 and rejected 37; the joint conference or joint committees accepted 145 and rejected 45; and one request was accepted and one rejected by the president. At the end of the six months 18 other questions were still pending. In this period, then, a total of 368 requests had been raised, of which 245 were accepted and 105 rejected. The particular problems dealt with are significant. Fifty-four per cent. involve working conditions, (improvements to protect employees and to facilitate their work); twenty per cent. living conditions, (mostly questions dealing with the maintenance or rental of company houses); 7 per cent. matters of

employment, (hiring or firing); 6 per cent. wages; 3 per cent. recreation; 2 per cent. medical help; while the rest were scattered.

It can readily be understood from all this that the plan is a cooperative mechanism between employers and workers which achieves results. An average of nearly two questions per day have been adjusted, over half of them through the joint conferences and joint committee meetings. Seventy-four per cent. of all the requests related to working or living conditions. And sixty-six and five-tenths per cent. of all those brought up by the employees were settled in their favor. The number still pending represent less than one per cent. and deal mostly with living conditions. The president's industrial representative in a letter dated July 27, 1922, states, "The need for extreme measures of economy account for some of the rejections and caused deliberate consideration of those which were not finally disposed of in the six months period."

It is apparent that the company has the last word in all questions and that its decision is final except that appeal may be made to the State Industrial Commission; but in any case there is an enormous advantage in having grievances frankly stated, discussed, and so far as possible, adjusted. If the Tsar of Russia had been willing to have open communication with his subjects, to permit the Duma to meet and discuss all questions that were troubling the people, he might still be in power. In a similar way any concern which frankly permits the employees to raise any questions they like and then settles them on the basis of joint discussion has gone a long way toward solving the human mechanics of industry.

Without considering the actual cases which come up for settlement, it is impossible to realize the extent of the advantages accruing to the workers from a plan of industrial representations. Let us consider concretely, a few of those taken up by the company superintendents. John Cortez, 17 years of age, complains that he has been discharged. Investigation discloses that he was no longer needed because a locomotive has displaced the mules which Cortez used to handle. He is assigned work clearing roads and assisting the masons, but this does not satisfy him; he is next offered a chance to dig coal with his father, an experienced miner, but he refuses and the case is closed.

At Primero, the miners complained regarding the weights received on their cars. A committee was authorized to be present when the inspector tested the scales and found them ten pounds too light. This case illustrates the advantages of the system. A real injustice was being done the men. Under the old autocratic boss method, their complaints might have gone unheeded while the injustice rankled in their minds until it caused an explosion. Under the new policy the matter is settled satisfactorily to all. Such a small improvement as the installation of ice cold drinking water in the iron department may prevent an enormous amount of potential friction.

Some decisions are settled against the men. For instance, Gus Carlson, adjuster in the field fence department, objected to being worked three days as an adjuster and three days as an operator. He preferred straight time as an operator. He was told, "It is to the best interest of the company to direct the working forces."

All the men seem to feel that the plan prevents the boss from arbitrarily discriminating against a man

or firing him. For example, Joe Cardo who was discharged for abusive language toward Craneman Stalling, took his case to the superintendent and was placed elsewhere. Foreman Shultz declared Joe Mignome was too slow and dangerous. Joe protested and investigation by representative Helm among the men on the foundry floor did not corroborate the charge; Mignome was retained at his task. Under the old policy of hire and fire, Joe would have a permanent grievance which might break forth into trouble in time of crisis.

To understand the type of questions considered at the Joint Conferences, let us take up a few of those settled by the last Trinidad Conference.

1.—A lighting arrangement was installed at the Morley railroad crossing.

2.—Porches were ordered constructed for the houses above Berwind.

3.—Charges for soft drinks at various Y. M. C. A.'s were adjusted to agree with prices in neighboring towns.

4.—Lights were ordered installed in the garages of the miners.

5.—Basements under tenant houses were ordered constructed at a cost of fifty thousand dollars.

6.—A request was made for the Santa Fe train to stop at a certain crossing.

7.—An increase in the bath room facilities at one of the mines was urged and adopted.

8.—The cost of board at a certain camp was made uniform with others elsewhere.

9.—The excessive cost of powder was discussed but the company explained that the slight profit now was only balancing money previously lost.

Each of these questions was taken up, discussed, and settled. Perhaps enough has been given to show the importance of the conference plan. It removes the gnawing sense of injustice which men feel over little things which can be corrected. In addition, it is the way to permanent improvements such as attractive homes for the workers, bath houses, club buildings, and splendid schools. In some places swimming pools have been installed. The contrast between the housing conditions in the Colorado Fuel and Iron Company properties where the houses are neat and the gardens thriving, and those of some other concerns where there are miserable shacks hardly fit for cattle to live in, is striking.

As a result of talking with representatives and men, the writer found the following general agreement as to the merits of the system:

1.—It brings the men, the foremen, and the superintendents together.

2.—All minor grievances are equitably settled.

3.—It has improved working and living conditions in the concrete ways we have enumerated above. "Today a man even makes the rounds to carry away our ashes," said one worker.

4.—Most of all, it prevents discrimination and graft on the part of the foremen. A man cannot be discharged without cause.

Against these advantages the following objections were raised:

1.—Men who are in the union will not give the plan a fair trial.

2.—Far too few employees take an interest in the plan.

3.—It provides no real method of settling wage disputes except by yielding to the company.

4.—The employees cannot bargain on a national scale; they have no fighting fund with which to enforce their demands, and must yield to the decision of the company or go elsewhere.

5.—The plan harms the union.

We have already considered in some detail the advantages of the plan. The most important objection, that it hurts the union, is serious because the labor union is the chief protection that the coal workers of America have against an unjust wage. Theoretically, the plan takes a position of absolute neutrality towards unions. It says, "There shall be no discrimination by the management or by any of the employees on account of membership in any union." It is one thing to have such a rule and another thing to enforce it. For example, in one of the mines a union representative urged his fellow employees to refuse a wage cut and to strike. Later, after sixteen of the men had gone out, he was informed that he would never be reemployed although the mine superintendent admitted his superiority as a coal miner. Instances of this kind could be multiplied. There are always some superintendents who do not live up to the spirit of a plan and it is hard to enforce the matter from above. Then, too, there is ever the difficulty of deciding how far a union man is justified in making propaganda against the company. Certain it is that the actual results of the plan have been such as to hurt the unions. In a conference of all the representatives from one district, the following statement went unchallenged, "Every man in this room would have been in the union had they not had the Rockefeller plan." In other words, all the representatives agreed that it had hurt the union by decreasing complaints and points of friction.

To a certain extent, however, this very charge is a testimonial to the success of the system in settling grievances, inaugurating better working conditions, and inculcating a more harmonious spirit between manufacturer and men.

From this study it is apparent that the Colorado Fuel and Iron Company have honestly tried to better relationships with their men. The first steps in contact, cooperation and representation have been taken. Officials of the United States Steel Corporation laugh at the plan as a joke; but the company's sincerity has been demonstrated by a seven years' trial and by the improvements already made, not the least of which has been the abolition of the twelve-hour day. Those who believe strongly in the unions, should nevertheless admit that every honest attempt to bring harmony into industrial relations is a step in advance. The Colorado Fuel and Iron Company are pioneering the way to something better than the old Tsarism of the United States Steel. In the seven years since they inaugurated the plan, four hundred different concerns, employing seven hundred and fifty thousand men, have put in similar plans.

It is a revolutionary movement. If conducted honestly, it provides opportunity for the workers to secure training in representation and initiative. It is not an impossibility that the very company union may some day take the bit in its own teeth and affiliate with organized labor. At the very least, it does accomplish constructive results in improving living and working conditions which too often the union as a fighting agency neglects.

America has achieved democracy on the political side; she is slowly struggling through unrest, strikes, and legislation to reach some form of industrial democracy. In our age every executive must sooner or later consider whether or not he has introduced into his own business even the rudimentary principles of the human mechanics of industry. Has he striven for contact with his employees, for representation, and for cooperation? The plan we have discussed is one of the honest experiments which have achieved good results and merits consideration as one road leading toward industrial peace.

### THE ST. LAWRENCE

A \$250,000 investigation, paid for by American capitalists, has been completed. The investigator was Hugh L. Cooper, the engineer responsible for the Keokuk and Muscle Shoals dams. The results appeared in a recent article in the Outlook, by Newton Feussle.

The river could supply 5,400,000 H.P. It could save 54,000,000 tons of coal annually, thus releasing \$550,000,000, now tied up in railroad property, for other uses. Its use would reduce the power bills of Canada and the United States \$189,000,000 per annum. Grain freight rates would be 6 to 10 cents less per bushel.

Colonel Cooper suggests the building of five dams, six locks and six miles of canal, thirty feet in depth, in the 120 miles between Ogdensburg and Montreal at a cost of \$1,250,000,000, roughly four times the cost of the Panama canal.

The great physical obstacle would be the ice which for a period of ten days each spring goes through at times at the rate of 675,000 tons per hour.

Today there are transported 44,000,000 tons of freight annually over the river. Canals would make possible the handling of 200,000,000 tons per season. Despite the fact that in 120 miles the river falls only 220 feet the cost is figured at \$17 per horse power per year, exclusive of taxes. This compares well with prices at Niagara, being in fact less than average costs from new installations, today.

It is submitted that power can now be commercially transmitted 400 miles and that the St. Lawrence development would thus affect, directly, fifty millions of people, quite regardless of the importance of deep water navigation from the lake ports to all parts of the world.

### RICH OIL SHALE IN ESTHONIA

In Esthonia, the little new republic just south of the Gulf of Finland, there are beds of oil shale of unusually high grade. The combustible matter ranges from 36 to 45 per cent. and distillation gives a yield of oil of about one-quarter the weight of the shale. Some small shale-oil plants were in operation during 1921 and 1922, and it is expected that large distillation works will be in operation shortly. The shale can be burned by itself, and has a calorific value about one-half that of the best coal. It is already used extensively as a domestic fuel, in gas works, and to fire cement mills.

# China Clay in Cornwall

AN INTERESTING VISIT TO THE CORNISH CLAY  
MINES OF MESSRS. H. D. POCHIN & CO., LTD.

By W. TRETHEWAY

A map of Cornwall showing the numerous China clay mines of the firm of Messrs. H. D. Pochin & Co., Ltd., is sufficient to demonstrate the wide-spread and important operations of this well-known firm. For the benefit of our readers I made a special visit to some of their China clay mining operations on a recent Saturday afternoon, and obtained quite a revelation of what sound business experience and a supervisory control, combined with the requisite resources of a well-established firm, can achieve. It will be impossible to trace with more than a small degree of exactness the progress and development of this world-famous firm even as far as it concerns the China clay industry. They are undoubtedly great architects in the commercial kingdom, and their large establishment with business tentacles in so many directions and in all parts of the world is practically the evolution of three ideals constantly pursued by this firm for more than a century. The first relates to the quality of the goods, the second, promptitude in despatch, and the third, the efficiency of their business system.

More than half a century ago the late Mr. H. D. Pochin discovered a process for the manufacture of aluminous cake using China clay as its chief ingredient. This new form of alumina, which became so largely used by paper makers throughout the world, proved a notable triumph for the firm, who were then more concerned in the manufacture of chemicals. The firm were even at that period fairly large consumers of China clay, but the demand for their aluminous cake exceeded their most hopeful expectation and necessitated the acquisition of their own China clay mines. As a result the famous Gothers Mine in the parish of St. Dennis was acquired in the early seventies. Gothers Mine at that period was but a small proposition for the firm of H. D. Pochin & Co., Ltd., and under the early direction of Mr. William Pochin the capacity of this mine was revolutionized. It was at Gothers that the gas engine for pumping and also for winding was first introduced, which is now rapidly usurping the place of the old Cornish steam pumping engines.

There are six very large drying kilns and the drags and tanks are ingeniously surveyed and constructed with a view to the elimination of all impurities as well

as effecting the utmost economy. Over 40 years ago a light railway was constructed linking up each of the kilns with the main line of railway, passing through a couple of miles of the famous Goss Moors owned by Lord Falmouth.

The storage capacity of clay ready for shipment at Gothers is nearly 6,000 tons, which enables the firm to accelerate large shipments when required, and represents nearly 60 years output of its earliest production.

An important expansion that followed was the acquisition of the Balleswidden and the Leswidden Mines in West Cornwall, and the extension of the loading facilities at the Penzance docks. At Parson's Park, situated north of Liskeard, the deposit has more than met the Company's anticipations. Here the appliances of production were brought up-to-date by the addition of a powerful water turbine and a gas engine. The mine is connected with a drying kiln at a distance of nine miles by an earthenware pipe line and is linked to the main Great Western Railway line at Liskeard and also with the Looe Railway, at which port the firm have secured private facilities for loading.

It was, however, subsequent changes that marked such a momentous era in the history of Messrs. H. D. Pochin & Co. Ltd., whereby their productive capacity in China clay alone approximated 200,000 tons per annum. This was the possession of Gunheath, a mine with a world-wide reputation, as well as South Caudledown, South Goovean and the Wheat Remfry China clay mines, together with several well known China stone quarries and grinding mills and also a valuable Ball Clay deposit at Mainbow and Newbridge in Devonshire. From whatever standpoint such enormous expansion is viewed, there are two characteristics, enterprise and energy, that seem to stand out as the hallmarks of the firm from its inception.

The cordial relations that exist between the firm and their employees have also contributed largely to the unobstructed progress reflected throughout their long commercial life. Messrs. H. D. Pochin & Co., Ltd., recognise that the men are quite as anxious as themselves to get to work and do their bit for the progress of the industry.

South Caudledown China Clay Mine

Although I have frequently been in the vicinity of the Gunheath Mine, this occasion was practically my first visit to the Works. This mine, which has had a great reputation for more than a century, had been in the possession of the Higman family who have been associated with the China clay industry for the past century. I was received at the works by Captain W. Kelbow, accompanied by Mr. J. W. Higman, Jr., who is a son of Mr. J. W. Higman, the former proprietor of the Gunheath Mine, and who, I was glad to observe, was fulfilling the highest traditions of an illustrious family and fully maintaining a *clarum et venerabile nomen* in the China clay industry of Cornwall. This mine has evidently been one of the bright spots throughout the period of trade depression. Its native blue clay, so adaptable for a variety of uses, has maintained such a steady demand that no slack time has been experienced by the clay-workers. During the reconstruction of the new dry micas and the pipe line connecting the micas with No. 2 and No. 4 kilns, the firm found employment for only 50 men, but now on completion they have returned to their normal engagement of 110 men. Mr. Higman informed me that the

installed in the pit, a 120 h.p. gas engine generating electricity for an electric motor-driven centrifugal pump which, with the Cornish engine, has a total pumping capacity of 1,800 gallons per minute. The winding of the whole of the sand is done by a 65 h.p. Campbell gas engine.

The clay is washed on the hydraulic system, which gives the highest satisfaction. As soon as the clay water reaches the surface its refining process is begun. First it passes through a series of "micas," which consist of from 15 to 20 troughs, about 1½ feet wide and 220 feet long, constructed of concrete, where the sand settles out. At the bottom the clay has to pass through a succession of very fine gauze traps, which eliminates floating impurities and foreign matter. From here the clay and water pass into settling tanks, where the clay slip settles to the bottom and is then filtered, while the supernatant water is drawn off. The old settling pits and tanks have been improved and several new ones constructed to provide the additional output required. These extensions and the new kilns have been built from the designs of the firm's own engineer.

The kilns are advantageously connected with the

Gothers Deep.

excellent brands produced at Gunheath were the G. H. and G. H. R. native blue clays and the H. D. P., a superior pottery clay. These have met with such great demand from the paper making, bleaching and pottery markets, both at home and abroad, that the productive capacity of 125 tons per day has been insufficient to meet requirements. Looking down into the pit from the old engine house one is induced to ask why a larger hole had not been made after nearly a century's working.

There can be little if any anxiety entertained by Messrs. H. D. Pochin & Co., Ltd., regarding the future of their enterprise as the clay is known to exist far beyond the present workings, and even if the demand were doubled or trebled the deposit would not be exhausted within a measurable term of years.

The equipment of this mine includes some of the newest, as well as some well-tried engines. In addition to the large Cornish engine, erected in 1847, there is

railway line and Gunheath forms the terminus of the Bugle and Stenalees branch of the Great Western Railway.

Acting upon the special request of Mr. David T. Taylor, the General Manager, who is following in the best traditions of the firm, I accepted the invitation to see the South Caudledown Mine, about a mile distant. This mine, although more famous than Gunheath on the point of quality, presents quite a different problem to the proprietors, which, however, they are undertaking with their characteristic energy. This pit is hard to describe. It resembles a white ravine penetrating to a great depth and is long and narrow. It is bounded on one side by granite dykes of large dimensions, rendering the extraction of the clay concealed underneath an unenviable task. Mr. Higman informed me that the development of this mine was an expensive proposition but the firm were determined to use their best endeavours to make it a success. The

Gunheath Pit

# Humidification

A PROPONENT OF STONE DUSTING IN COAL MINES DESCRIBES ITS USE

BY JAMES ASHWORTH

This subject and its application to the coal mines on this continent appears to arouse almost continuous discussion amongst the engineers whose duty it is to make coal mining as safe as it is possible to make it.

The latest addition to the voluminous literature that has been printed in the engineering and mining journals and in the transactions of institutes and societies devoted to mining, is a paper entitled "Economical Humidification". This was contributed to the Coal Mining Institute of America, and although like the work of many other authors, no useful suggestions are made, yet it proves that the subject in its practical aspects is not by any means devoid of points of great importance. The author has, however, wasted his energies in an endeavor to show that he can conserve or economise the heat of steam humidification by passing it through the goaf of a coal mine. The writer of this article does not propose to criticise all the author's suggestions, but only to state his conclusion that any such conservation of heat is entirely visionary and impossible, because there is no possibility of finding in any coal mine on this continent goaf hot enough to prevent the condensation of steam, nor yet preserve its latent heat. It will be obvious to any student, or to any one practically acquainted with the management of coal mines, that there are a host of reasons why these suggestions are totally impracticable.

## *Use of Water Made Compulsory*

Before discussing the general subject of humidification, it may be useful to ascertain what is the present and past history of this detail of colliery management. Many years ago, coal mining officials thought that firedamp was the principal danger that had to be provided against, but as years passed by it began to be realized that there was another danger, and that danger was coal dust. Many, many more years have since been devoted by scientists and observant men connected with coal mining to experiments showing the great and unrecognized danger which is caused by the presence of fine coal dust in mines. Even at the present day, we cannot say that this danger is universally recognized.

Eventually, it was recognized by the British Government that there was a lurking danger which in ad-

---

narrowness of the pit precludes the use of the usual winding operations for the present, but arrangements are being made for its ultimate adoption. Here again the inventive mind has been active and this mine was the first to adopt the Blondin method of removing overburden. The deep brands of clay produced at South Caudledown are in greater demand than can be provided, both among the paper and higher grade pottery manufacturers.

The destinies of this large group of China clay mines are in the capable hands of the Chairman, the Hon. H. D. McLaren, C.B.E., M.P., and the Managing Director, Mr. H. Stanley Pochin, J.P., whose guiding influence and inspiring genius are followed with great interest by the whole community.

dition to firedamp was accountable for many great disasters in collieries, and that this danger was not provided against by ventilation and the regulations then in force for the safe working of collieries. Consequently, a Royal Commission was appointed to report on the Prevention of Explosions from Coal Dust in Coal Mines. This commission eventually reported that applications of water were the best preventive, and ultimately the laws governing the safety of mines made watering compulsory. At that time the amount of water used and the form in which it was to be applied were not fixed by law; consequently some mines were dampened and others, such as mines 1,500 feet deep or deeper, were not artificially watered. In the latter cases it was found that the miners could not work with efficiency unless the ventilating current of air was kept as dry as possible. A proof of this was obtained when two members of the Coal Dust Commission went down into the deep mine at Pendleton and had a bucket of water thrown over the coal that was being got on the inbye side of them. This rendered the air so moist that it seriously inconvenienced them, and demonstrated that watering was an impossible safeguard in such cases. Further, it has been proved by a well known authority on the rate of explosion in mixtures of explosive gases and air (Prof. H. Dixon) that the most violent explosions occurred when the mixtures contained 25 per cent. of moisture, that is when the moisture was in the form of steam. These experiments, therefore, indicate that any moistening of the air of a coal mine as a means of safeguarding it against the propagation of the flame of an explosion, must be in excess of 25 per cent.

## *Water of Limited Value Only*

With these provings and facts clearly set before coal mining officials, the writer of this article cannot see why so many people connected with the science of mining still insist that there is a safety value in any form of dampening or humidifying the ventilation current of a coal mine.

If, further proof of the limited value of water as a protection against the initiation of firedamp or coal dust explosion or for the arresting and limitation of the extent of an explosion, we only need to study the records of the very large number of experiments made under pit conditions in England, France and other countries in Europe to find that the use of water cannot be depended on as a safeguard. Again, the very long and careful experiments made by the United States Bureau of Mines at Bruceston proved that where mines are to be safeguarded by applications of water, they must have it applied in such generous quantities that the coal dust when taken up in handfuls is so saturated that water may be squeezed out of it. These conclusions, when stated in percentages, mean that not less than 53 per cent. water must be mixed with the dust throughout a coal mine to render it in any sense a safe mine, particularly where the coal is mined by coal cutters and where the coal is broken down by the use of large charges of explosive, no matter whether it is by a permitted or black powder explosive. This conclusion is irrespective of whether or not the

ventilation of the mine is suspended during the time when shots are being fired.

### *The Utility of Stone Dust*

In England and elsewhere, after the use of water had been extensively adopted as a safety provision, it was plainly demonstrated that water was not a true safeguard and that great disasters still occurred. These disasters were unmistakable evidence that something more practical and effective than water was urgently required. The discovery was then made that if very fine, non-inflammable stone dust were distributed on the roof, sides and floor of the haulage roads in such quantities that it became mixed with the coal dust to the extent of 50 per cent., it then became a protection against both the initiation of an explosion and also a means of arresting the flame of an explosion.

The protective value of non-inflammable stone dust is greatest when it is floating in the air, and thus where some engineers use a dampening arrangement in addition to stone dust, the protective value of the stone dust is probably lessened as there is a tendency for both the coal and the stone dust to separate out of the air and fall to the floor. In this regard, it is believed to be practicable to lessen the quantity of stone dust floating in the air by dividing the mines into zones where shelves containing large quantities of stone dust are so placed, and balanced, that on being disturbed by vibration they deliver their contents into the passing air current and thus limit the extent of the flame of an explosion.

Experimental tests made with safety zones arranged as above appear to have given very satisfactory practical results, but they have not yet displaced the use of water.

### *Uniform Regulations Suggested*

The United States of America possesses a most valuable scientific and practical department at Washington known as the Bureau of Mines, but its work and

discoveries with regard to the economical and safe working of mines is not reflected, to the extent it ought to be, in all the States of the Union. Thus each state has its own code of rules for the regulation of mines, and it appears to the writer that the safety of coal mines throughout the States of the Union might be vastly increased if the rules in force in all States were consolidated by an Act of Congress. The same conclusion applies to Canada.

A drastic consolidation such as this would without doubt increase the safety of mines, and the valuable work of the Bureau of Mines would be brought into effect with rules for safeguarding coal mines against coal dust dangers, whether by humidification or by non-inflammable stone dust, or by both together, and also the use of explosives and the lighting of mines would be placed on a firm basis. "Safety First" would thus become something practical and the fallibility of man reduced to a minimum.

In conclusion, the writer would rejoice to hear that some energetic member of our governmental body had taken up this subject with a vim, and that a code of rules applicable to all our provinces had been compiled and brought into daily and hourly effect.

\* \* \*

Since this article was written two very serious explosions have occurred, one at Dawson, New Mexico, and the other at Cumberland, British Columbia. At both these mines there have been previous fatal disasters and clearly whatever protective means have been applied to prevent or restrict the extent of an explosion, they have proved an entire failure. Both these cases and others that have previously and recently occurred emphasise the fact that humidification as a protection against the extent of either a firedamp or coal dust explosion or both combined has proved an entire failure. The case demands the Legislative and Engineering attention of all the coal mining States of the United States of America and also of Canada.

## News and Comments

BY ALEXANDER GRAY

### *They Were "Astounded" — And So Are We!*

Clearing the hurdles, taking everything there is in the obstacle race with a rush, *The Montreal Star* commented on the gold returns from Northern Ontario, by displaying this—

### *"CANADA IS NEARING RAND GOLD OUTPUT"*

There are those who may proceed upon this information and load up with a bushel or two of "securities." The pre-ordained objective being within reach, according to headline writers, it is a quite inconsiderable matter that South Africa is just celebrating its £1,000,000,000, golden achievement. Nor is it necessary to put the actual facts "under the glass." The editor who went pole-vaulting landed in a manner pleasing to the most optimistic. If there is any doubt about it the linotype operator was at fault—for not having made it a little stronger.

Last year Canada is credited with having yielded £5,300,000 in gold; the Transvaal, £29,800,000. Forty days having intervened, it became a matter of easy

assumption to extend Canada's 17.77 per cent. of the Rand total in a year of prolonged strikes, to within a trifle of the Rand production. This is not at all astounding, considering a recent prospectus suggesting that one Porcupine prodigy had ore that meant a daily production of \$4,500,000. Working 300 days at that rate would give \$1,350,000,000; so one mine (if nothing interrupted operations) may in five years make Rand pretensions to pre-eminence look like a second rate reminiscence!

Mr. Brigham, shedding effulgence and aiming to be deliciously sanguine, was quoted as surmising "there may be a hundred Hollingers here, for all we know." Keeping in reserve the hypothetical \$27,000,000,000 possible from Labrador, it is feared a section of the laity and their editors may indulge in under-estimations. Nor are we alone in our apprehensions in this respect, since James H. Curle visited Northern Ontario, aroused London, then started for Nyassa, incidentally dropping in on Johannesburg, and invited this, which appeared in *The African World*.

"After astounding his old pals in the Golden City, with his view on the immense wealth of Ontario, Mr. Curle left the Rand for Nyassaland, where no mines have been discovered yet—but—"

#### *A Globe-Trotter's Shrewd Opinion*

Here in Canada there is satiety; yonder Mr. Curle planted comingled suspense, astonishment, and (we hope) a perfectly laudable purpose to convince "the Groups" that the pre-Cambrian formation has the wealth-giving attributes of their unique banket—those pebble beds that contributed gold at the rate of nearly £30,000,000 for 1922. To have Mr. Curle do this where the Gold Mining Aristocracy was, and is, supreme, may have been "astounding." He is a very frank person. For many years the pains and pleasures of his comments have permeated all gold fields. As a Commissioner of the Empire he has flitted to and from all quarters of the globe—lately in Northern Ontario, today in equatorial Africa—and the solidity of his reasoning never has been gainsaid. The author of "Gold Mines of the World," having roamed at will, never has been a constructive critic, sufficiently detached to have an open opinion and to be able to express it.

Dismissing the slight miscalculation of *The Star*, and making due acknowledge to the Rand for its unparalleled performances, it is significant that the London Editor quoted employed the past participle, which, accurately conjugated, brings satisfaction to those who look to the Rand Magnates, so-called, for participation in Canadian developments. The astonishment occasioned by Mr. Curle, no doubt was all the greater because he is a weigher of words. It was characteristic of him to drop around to Goldopolis and "sound the loud timbrel" at the witching hour when the "Corner House," Gold Fields, Consolidated Investment, General Mining and the other abodes of influential Central Administrations are more amenable than they used to be to outside suggestions. Yet it is almost incredible that Mr. Curle's old pals were "astounded," in view of their wonted imperturbability. Conceding how surprising it is to have it emblazoned "along the Reef" that Ontario for the next twenty years will be the most attractive gold country, it is highly improbable that the chief factors at the Rand are uninformed as to what is transpiring at the Canadian gold fields. What Mr. Curle said may make them more receptive and bring their card index up to date. If they have not bestirred themselves hereabouts, it is not because of defective intelligence maps. They are the most avid of the species; they foresee gradual recession in their aggregate output; if they are aloof the blame therefor does not rest with them alone.

One of these days the London-South African Groups will take Canada more seriously, and Canada will accord more favorable terms to them. Mr. Curle has helped to broaden the horizon, without asserting the Rand will have a rival. And here it may be parenthetically noted that the Rand was so constituted that it was financed on a premium basis, whereas western precedents adhered to the discounts deemed essential in hasty financing. As a rule, Rand mining principals do the discounting to start with; but they taught others the worth of gold fields, and it is an exaggeration to say that they or any of their compeers were "astounded" by the statements of Mr. Curle.

#### *The London Viewpoint*

Apart from the mingled feelings attributable to Mr. Curle, it is more "astounding" to have him bestow his

fulsome tributes upon the Northland, and to do it unreservedly. It is almost twenty years since he jarred my tympani. Chatting with him in London Wall during one of these periods when he was not boxing the compass, I was expounding the superlative qualities of the Rand, contending that the deep depths and extensions east and west left no room for doubting. The man, whose nervous organization at the moment was giving anxiety to his intimates, curtly remarked "Oh, you have lived in the Colonies too long!" In other words, one had to change his environment, travel, and "take the air" in "the City" betimes, in order to have the right perspective, to get rid of provincial optimisms.

No more comprehensive observer ever went on survey. We may not coincide with him and think this is a small universe outside of London, from whence and to which all roads lead, where propositions from the four quarters of the world are daily proffered. So and so many proposals always are at flood tide in London. Lotharios from everywhere reckon themselves to be irresistible, but the Old Lady of Threadneedle street is discriminating. Consequently, when suits are pressed too strong, the claimants for favors meet the undisguised reproof:

"Oh, you have lived in the Colonies too long!"

There is something in that comment, when it comes from the methodically constructive and economically conservative, who are willing to frolic with funds without dissipating them. When all is said and done, and cooling processes have been applied, London and what it represents have provided the greater portion of the world's working capital, by scientifically taking the world at its worth. That and no more is what Canada should maintain as a policy. Canada desires to be invited to tender on sound bases, and not to have it felt between Bishopsgate street and the Bank, Cannon street and Moorgate, that the third table is reserved for London. Mr. Curle is as "cold" as the proverbial "chastity." Canada is indebted to him for his dispassionate propaganda, voluntary and disinterested and on other than economic account. It remains to organize forces that will be mutually compensatory.

#### THE NEW MONTANA OIL FIELD

One of the papers to be presented this week at the New York meeting of the A. I. M. M. E. deals with the Sunbrust-Kevin oil field in Montana, just south of the border at Coutts, Alberta. There are now 29 wells producing oil, and six gas wells. There have been 6 dry holes, and 4 at present dry that may produce. Thirty wells are in course of drilling.

There are two producing horizons, the Kootenai and the Ellis, and the production per day at present is 2,200 barrels. The possible productive area is 212 square miles.

#### RAND WATER SUPPLY

The supply of water for the Rand, South Africa, has always been a difficult problem. It has now been adequately provided for by a dam of the barrage type, 1,400 feet long, across the Vaal River 25 miles below Vereeniging, which has recently been completed. The flow of the Vaal river varies extremely with the seasons. The dam will back up the river for a distance of 40 miles, and provides a reservoir holding a maximum of 13,633 million gallons, the maximum depth being 25 feet at the dam. The dam and the superimposed bridge have cost £477,000.

## PROGRESS IN CANADIAN WATER POWER DEVELOPMENT\*

One of Canada's greatest resources is comprised in its wealth of water powers. In this respect the Dominion takes second place only to the United States in the extent of power available, maintains the same relative position in horse-power available per capita of population, following Norway, and again occupies the second place after the Scandinavian country in per capita hydro development. The development of Canadian water-power resources has been a prominent feature of national progress in recent years, and probably no other industrial factor has been so largely responsible for the employment of capital and indirectly for the development of other industries. The bearing of Canada's great water-power resources upon the future manufacturing status of the country is significant and is rapidly transforming the Dominion from a country almost wholly agricultural to one in which manufacturing interests are of great and growing importance.

There has just been published by the Dominion Water Power Branch a further and up-to-date statement of water-power development in Canada, covering the period up to November 1st, 1922, and this reveals the substantial progress effected in the past few years in hydro development in all parts of Canada and the greater part Canada's water-powers have, in the last decade, come to play in the Dominion's industrial life. The recorded power available throughout the Dominion, under conditions of ordinary minimum flow, is 18,255,000 h.p. The water-power available under estimated flow for maximum development, i.e., dependable for at least six months of the year, is 32,076,000 h.p.

An analysis of the water-power plants scattered from coast to coast gives an average machine installation of 30 p.c. greater than the six month flow maximum power. Applying this, it becomes apparent that the at present recorded water-power resources of the Dominion will permit of a turbine installation of 41,700,000 h.p. In other words, the present turbine installation represents only 7 per cent. of the present recorded water-power resources.

### *Recent Progress*

During the year 1921 the readjustment of values following war-time inflation made substantial progress, but necessarily brought in its train many business and financial difficulties and a lack of confidence in trading circles generally which led to a reluctance of capital to embark upon new enterprise. It is a remarkable fact, however, that the hydro-electric industry, though naturally affected by the general depression, suffered no set-back, and in fact the horse-power installed during 1921, 300,000 h.p., stamps 1921 as one of the most progressive years in Canadian water-power history.

The 2,269,659 h.p. at present installed throughout the Dominion is apportioned to the following uses. A total of 2,164,870 h.p. in central electric stations for general distribution purposes, such as the operation of street railways, operation of mines, operation of electro-chemical and electro-metallurgical industries,

operation of pulp and paper mills and for general industrial, municipal, and domestic use. A total of 489,228 h.p. is installed in pulp and paper mills. In addition there is used in the pulp and paper industry 160,577 h.p. purchased from the central electric station installation. A total of 320,561 h.p. is installed in industries other than central electric stations and pulp and paper mills. The total installation for the Dominion averages 338 h.p. per thousand population, a figure which places Canada second only to Norway in the per capita utilization of water-power among the countries of the world.

### *Central Station Industry*

By far the most important use to which development of water-power has been applied in Canada has been in connection with the central electric station industry. The extent of this industry and the important relationship which power bears to it is measured by the fact that 97.2 per cent of the power actually generated is developed by the use of water-power and that there is now invested some \$501,400,000 in hydro-electric plants and systems engaged in the production, transmission, and distribution of electrical energy for sale.

Throughout the Dominion there are 269 hydro-electric central stations with an installed turbine capacity of 2,164,870 h.p. or a generator installation of 1,633,140 k.v.a. It is of interest to note that of this total turbine capacity 1,501,491 h.p. is installed in commercial or privately owned stations, while 663,379 h.p. is installed in municipal or publicly owned stations.

### *Past and Future Growth*

It is interesting to note the growth of water-power development in Canada during the past decade. Since 1910 the total installation has grown from 975,000 h.p. to 2,970,000 h.p.; the central station installation from 605,000 to 2,165,000 h.p.; and the pulp and paper installation from 191,000 to 484,000 h.p. The average yearly increment in the past decade has been in excess of 180,000 h.p. installation.

Should the rate of water-wheel installation during the past twelve years be maintained there will be installed in 1925, 3,360,000 h.p.; in 1930, 4,110,000 h.p.; in 1935, 4,860,000 h.p.; and in 1940, 5,600,000 h.p. In view of the increasing appreciation of the advantages of hydro-power, combined with the fortunate location of ample supplies within easy transmission distance of the industrial centres throughout the Dominion, there is every reason to anticipate that this rate of growth in utilization will be accelerated rather than retarded. This will not seriously reduce the total reserves, for Canada possesses sufficient reserves to meet all anticipated demands for many years to come.

The water-power now developed in Canada represents an investment of over \$620,000,000. In 1940, should the rate of growth outlined be maintained, this investment will have grown to well over \$1,100,000,000. The present development represents an annual equivalent of 26,700,000 tons of coal, which, valued at \$10 per ton, represents a total value of \$267,000,000. In the year 1940, these annual figures will, with the foregoing assumption, have become 50,000,000 tons and \$500,000,000. The figures are striking evidence of the outstanding importance and necessity of an intelligent administration and development of Canada's water-power resources.

\* From "Agricultural and Industrial Progress in Canada".

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**POWER TROUBLES.**—Power company troubles seem to be very much to the fore these days and mine operators in both Kirkland and Porcupine are complaining. In Kirkland operators claim that they are paying \$65 and \$70 for power with very frequent interruptions to the service, while the price charged in Cobalt and Porcupine is only \$50 a horse power year. They also complain of the clause in the contract that binds the mine during its life but does not bind the power company to supply power, and does not obligate the power company to provide for increasing needs. The capacity of the present line is only 5000 horsepower and the present consumption is about 3000; but with the proposed increases at the Lake Shore and Wright-Hargreaves its capacity will be taxed.

In Porcupine the low water and shortage of storage facilities have necessitated another cut to the consumers and although steam plants are being used to the limit of their capacity the producing mines will have to curtail either output or development work. The Sandy Falls plant on the Matagama river is not yet ready so that the mines will be short of power until after the spring thaws. During the coming season the Northern Canada Power Company will proceed with extensive developments at an estimated cost of \$1,250,000 which it is hoped will remedy the situation next winter.

In the meantime the Hollinger fight to secure power rights goes merrily on and despite the official announcement made a short time ago that rights had been secured at Island Falls on the Abitibi River, it is learned that this is not the case. The Abitibi Power and Paper Company state that their lease gives them the right to develop power and storage on the Abitibi River and that the company has received no notification from the Ontario government of any change in the terms of the lease. The Abitibi lease would have to be changed if the Hollinger were granted the terms it demanded. There is plenty of power on the Abitibi river for everybody, if it is properly handled, and people familiar with the situation are wondering if the Hollinger's anxiety for power on the Abitibi on its own terms, is not related to some far-sighted scheme which is not immediately concerned with mine requirements. The Northern Canada Power Company has an action pending against the Hollinger for the enforcement of a contract for the full requirements of the mine and it seems doubtful whether, even if the lease were obtained, power construction for mine purposes could be started until after this suit is disposed of.

**PROGRESS AT INDIAN CHUTES.**—Between 500 and 600 men are at work on the plant and transmission line of the Great Northern Power Company at Indian Chutes on the Montreal River and it is hoped to have the power in Porcupine by the end of May. The Davidson Mine, promoted by the same interests that are behind the Power Company, has contracted for this power and will not start underground work again until it is ready for use. Recent reports of diamond drilling on the Davidson show good values at 1700 feet, which is the deepest drilling done from the surface in Porcupine.

**MATACHEWAN.**—The British Matachewan Gold Mine has taken over a number of properties in the district and amalgamated them into one company. Considerable work has been done on one of these properties and some promising veins were found. The company also expects to take power from the Great Northern Power Company and it is anticipated that work will be started when power is available. Arrangements are being made to float the stock of this new company, in which case no doubt the public will as usual be asked to put up the money for a minority interest.

**PORCUPINE.**—Porcupine production increased during January, the Dome output for the month being over \$400,000. In the recent action brought by the Digby Dome, which owns adjoining ground, to restrain the Dome from putting tailings on the Digby land and to order the removal of those already there, the court granted an injunction, to come into effect in thirty days, prohibiting the placing of tailings on the plaintiffs' property. The court refused, however, to order the removal of tailings on the ground, but ordered a reference before the master in Brantford to determine the compensation. Application has been made before the Mining Commissioner for permission to deposit tailings on the Digby ground and this will be heard shortly. This Commissioner's judgment may be appealed and in the meantime the Dome will have to take measures before 30 days to see that no tailings are deposited. The amount of Digby ground at present covered by tailings is about twenty-five acres, and on account of the conditions it is very difficult to prevent slimes from depositing, and it will be almost impossible when the spring break-up comes.

The McIntyre has opened up new ore in a crosscut from the 1875-foot level. Assays are reported to run between \$30 and \$40 across 10 feet. The company is now getting the advantage of higher mill heads, which in January were about \$12 a ton. The option on the balance of the McIntyre treasury stock, held by New York Interests, will expire in a few weeks and it is anticipated that the stock will be taken up. The option price is \$15 a share and would result in \$1,000,000 being placed in the McIntyre treasury.

**KIRKLAND.**—The Lake Shore mine has decided to erect a steel head-frame 75 feet high as part of the proposed programme of enlargement. It is expected that in March construction of a 300-ton mill will be started, which it is expected will be placed in operation before the end of the year. Although sinking has not yet been started below the 600-foot level, the results of mine development have been very satisfactory.

The annual report of the Wright-Hargreaves for the year 1922 shows a gross production of \$762,752 and net profits of \$344,630 which is the largest output and profit of any mine in the Kirkland camp since mining was started in that district. The average recovery was \$11.52 a ton and the costs were \$6.31 a ton. The mill treated 205 tons a day or total of 66,181 tons for the year, and while ore reserves are not given, there are over 33,000 tons broken in the stopes. The report mentions the probability of an increase in the mill capacity when the shaft has reached the 1000-foot level. At the end of the year it was down 865 feet and sinking is

being continued. During the year dividends amounting to \$412,000 were paid and provision is made in the financial statement for the dividend paid in January. Current assets as of Dec. 31st. are \$274,125 and current liabilities \$108,414, while the surplus is \$6,424.

### BRITISH COLUMBIA

**THE CUMBERLAND MINE EXPLOSION.**—The explosion at No. 4 Mine, Canadian Collieries (D) Ltd., Vancouver Island, has overshadowed all other events of the past week. Thirty-three bodies have been recovered at time of writing and latest advices are that there are two underground still. It is known that fourteen white miners are dead. Of these nine were married, leaving thirty-one children of tender years, and five were unmarried. There are four married men in the hospital with good prospects of recovery. Nineteen of the dead accounted for are Chinamen.

Anything that may be said of the cause of the outbreak at present would be pure speculation. The deadly afterdamp is what caught, with fatal results, the majority of those whose names are on the death roll. The gas overtook its victims as they hurried to

Portal of No. 4 Mine, Cumberland, B. C., where Fatal Explosion Occurred.

safety, in one case fourteen bodies being found lying within a short distance one of the other. Experience and presence of mind saved James Finfold, who led fifteen Chinese through a maze of workings past the danger zone into the clean air of the main tunnel. Six Oriental miners refused to heed his warning and, taking a more direct route, were asphyxiated. Robert Walker, one of a rescue party, had a narrow escape. He was picked up unconscious with his head over a pool of water by men whose work was being personally directed by Charles Graham, District Superintendent of the Canadian Collieries.

No. 4 Mine, Canadian Collieries, is situated about two miles from the town of Cumberland and consists of two slopes with one main entrance. These slopes diverge at a point 75 feet distant from the main portal. No. 1 Slope is 7,000 feet in length, running due North. No. 2 Slope is 9,000 feet in length and runs North, 45 degrees East, being driven on the full dip of the seam. This results in its workings being the deepest of the mine. Levels are turned off this slope in an easterly and westerly direction, the lowest levels being Nos. 20-east and 20-west.

In longwall district, off No. 20-east level, No. 2 slope, an explosion occurred on the 30th of August last,

eighteen men losing their lives. The investigation that followed indicated that in this instance ignition was caused "by an arc in the electric trailing cable at the connecting socket used in connecting this cable with the main electric circuit." It also was stated that "it was a small explosion to take such a heavy toll ... Occurring on the longwall face it naturally brought a number of men in the path of the flame in a short distance. Owing to most of these men being engaged working on the face, and the seam not being very high, there was no way of escaping the flame."

The last explosion, it seems from reports thus far to hand, had its origin somewhere in No. 15-west level of No. 1 slope. This, of course, is an entirely different part of the mine from that affected by the catastrophe of five months ago. From the fact, however, that few of those killed appear to have been severely burned, it would seem that there is the similarity between this and the previous explosion, that the death list is out of proportion to the violence of the outbreak.

More specific information as to the cause, or causes, will have to wait on the report of Mr. George Wilkinson, former Chief Inspector of British Columbia, who was appointed immediately by the Hon. Wm. Sloan, Minister of Mines, to visit the scene and to make a personal investigation and submit a statement of his findings at the earliest possible date. With Mr. Wilkinson is Mr. James Dixon, Acting Chief Inspector, who is also charged to make an exhaustive inquiry, and who is assisted by Thos. R. Jackson, the District Inspector of Mines. It may be said incidentally that Mr. Jackson has made the statement that he visited the workings affected on the 29th of January last, finding no explosive gas and the working conditions good.

A word must be said in commendation of the splendid work of Rescue Crews. The men were quick to respond to the call for help. All during the night following the explosion they labored, never ceasing until all who had been underground were accounted for and there was no further chance of saving life. The facilities of the Government Rescue Station, as well as the equipment of the Company, were at their command. Thomas Graham, General Superintendent and Charles Graham, District Superintendent, did their utmost to assist. It is fitting, too, that acknowledgment be made of the offer of aid volunteered by the United States Bureau of Mines, Mine Rescue Officer Schoning of the Washington State Station having been instructed to proceed with men and equipment should his services be required. Although it was not necessary to take advantage of this evidence of international good-will, the spirit prompting the action was much appreciated by officials of the Mines Department of the Province.

The immediate distress of bereaved families was relieved from Provincial Government funds and those who were left without support will be taken care of under the Workmen's Compensation Act.

The Imperial Mineral Resources Bureau has published a 31-page report on *Aluminum (including Bauxite and Cryolite)*, which is composed of world statistics, 1919-1921, of these materials and compounds such as alum. The report can be obtained for 1s. 1½d. post free from H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2, or from the British Commonwealth Publishers, Ltd., in Montreal, Toronto, Ottawa and Winnipeg.

## NOVA SCOTIA

**THE STEEL PLANT STRIKE.**—The violent Labor agitation carried on among the Sydney steel workers during the last six months reached a sudden climax on the 13th. instant, when a steel worker refused to obey orders and was discharged. Without the least regard for the property of the Company or their own future employment the blast-furnace crew and others walked off the works right after McNeil, the man who was dismissed. The following day the strike was in full effect, and all departments were closed down. The Company succeeded in slowing down the coke ovens and will have sufficient men to keep these heated. The open-hearth and blast-furnaces were banked, but only with great effort on the part of the officials and a few faithful employees. If the workmen of this plant had been able to carry out their intentions, almost irreparable damage would have been done to the blast-furnaces and coke ovens, and unemployment for the next two years, at least, would have been general.

The Sydney steel works takes four thousand tons of coal per day, and while the strike continues, the collieries will be affected to this extent.

The following was a statement issued by the Dominion Iron & Steel Company, setting forth the case:

"At the meeting this afternoon with a committee representing the striking employees, Sydney McNeil admitted stopping some machines and ordering other helpers to stop theirs. The committee further admitted that McNeil refused to comply with the superintendent's instructions to start up his machines, and they claim that McNeil, a union representative, had the right to order these machines stopped. Superintendent Bischoff stated that on the men's own statement McNeil's dismissal was justified, and what the committee was asking was that the company should submit to outside persons its right to discharge an employee for good and sufficient cause."

According to the statement of the foreman, the discharged workman not only refused duty himself and hindered others, but was most defiant in his attitude. And yet the steel workers organization seems to be willing to stake its reputation on the outcome of such a discredited case. In such circumstances no labor union can hope to succeed, for the success of all labor organizations depends upon the control of the membership and a reasonable attitude towards the employer. Discipline there must be, and the glaring flagrance of this case sweeps aside all attempts at justification. The men's representatives openly declare that insolence to an employer by an employee is right and may only be resented at the peril of shutting down the whole works. The success of such a strike, at the cost of common civility to say nothing of the triumph of insubordination, would be the death of all organized industry.

That several thousand workmen should get behind an action that is condemned as soon as heard, is almost incredible; yet we seem to be living in an age when wild deeds and insensate language are cheered by the very men on whom they react most, robbing them of their contentment of mind, starving their bodies, and blighting their homes.

The strike cannot succeed; it is doomed the failure from the very beginning: and no matter how long it may last the baleful shadows will continue to deepen into the darkness and despair of a lost cause.

Intimidation does not adequately describe the work

of pickets at the steel plant. Like all bodies of men badly organized and led by irresponsible leaders, things have been done that in larger centres would not be tolerated under any condition. Railway trains have been held up and searched, the locomotive detached from the cars, auto trucks and other vehicles have been stopped, office workers, stenographers and officials forcibly turned back by bands of workmen carrying clubs.

**MR. HERD'S STUDIES IN BRITAIN.**—Mr. Walter Herd, mining engineer of the Dominion Coal Company, has returned from a business trip to the collieries of Great Britain. While there he paid special attention to mine loading conveyors, as used in the long-wall collieries. He reports that these are very successful and greatly reduce hand labor by the loaders of coal, who perform the hardest work to be done in a coal mine.

Coal loading conveyors were introduced into the Dominion Collieries some years ago, but on account of their great length it was difficult to get them round the short turns of a mine road, and consequently they were discarded before they had been rightly tried out. Since that time it has been growing harder and harder to get loaders for a coal mine, and the Dominion Coal Company put one of these conveyors into Jubilee Colliery, where it is giving first rate results. A great improvement has been made in the construction of the conveyors since they were first introduced, and it may be stated that before long numbers of them will be in use in every Cape Breton coal mine.

Mr. Herd also gave special attention to some methods of long-wall, especially those which might be found adapted to the coal seams of Cape Breton. Princess Colliery, Sydney Mines, is now partially under that system, but it seems difficult to get sufficient skilled labor trained to make a success of their method.

The drawing of all timber, according to Mr. Herd, is most essential to successful long-wall methods. This requires experienced men, and as yet there are few of these in Nova Scotia. Mr. Herd states that in some of the Yorkshire collieries not one prop is permitted to remain in the waste workings, and sums of money far beyond the value of a pit prop are often spent to have one of these removed, that a clean break may take place when the roof is settling down behind and near the face.

**THE RETIRING AND INCOMING DEPUTY MINISTERS.**—The Government Coal Mine Inspectors gathered in Halifax lately to bid good-bye to Mr. Hiram Donkin, late Deputy Minister of Mines, and also to meet Mr. Thos. J. Brown, who succeeds him as deputy head of the Mines Department. Mr. Donkin was kindly remembered by the Inspectors, who presented him with a nice set of pipes and a tobacco pouch.

Mr. Brown, in meeting the Inspectors for the first time, gave a short talk on coal mining. Referring to the duties of Mine Inspectors, he pointed out the great responsibility they carried, and the necessity of being fully alive to the causes of all mine accidents. "Disguise it as we may," said Mr. Brown, "the most prolific cause of mine explosion lies in having the air too far back from the working faces of the mine. This fact is well known to mining men everywhere, and we should see to it that all leading places and room faces are well ventilated. If these are kept

well mixed, the gas from veins newly cut and the dust made in tapping will be carried into return air ways and pass from these to the surface. If these precautions are neglected then we will not be able to prevent disasters in Nova Scotia, because we have not given attention to the prime principle of mining." Other phases of mining were touched on but the emphasis was laid on gas and coal dust. The inspectors returned to their several districts with the impression that Mr. Brown thoroughly understands the problems of mining, and intends that the Mines Department should carry its full share of responsibility in caring both for property and for the life and health of the miner.

**STEEL STRIKE OVER.**—Through the efforts of the OILERS' Committee the Sydney Steel workers returned to work on Monday after a five days' strike. Finding that the sentiment of the workers in general was strongly against a strike on behalf of McNeil, the discharged employee, though stampeded into leaving their jobs, and seeing that the men had no way of getting back honorably, the Steel officials made an offer to investigate the case after the men had returned to work. The men by an overwhelming vote accepted the offer and now all are at work. Few strikes have had less justification than this one, and it may be a long time before the men, many of them ordinarily level-headed, will permit themselves to be caught on the spur of the moment, interfering in any way with the discipline of the steel works.

Well-organized labor will not stand for any misconduct on the part of its members which, if countenanced, would undermine its own foundations. The strike is well over and with the heat of months of

agitation worked off, Sydney steel workers may have profited greatly by the reaction that comes from looking back at foolish and rash action.

### CANADIAN ASBESTOS IN GERMANY

The Canadian trade commissioner in Germany reports in the *Commercial Intelligence Journal* of February 17th, that during the first nine months of 1922 there was imported through the port of Hamburg 183,866 bags of asbestos, bags for Canada averaging 100 pounds each, and from Africa, 150 pounds. The total amount is approximately 11,500 tons. Most of this came from Canada, the Rhodesian and Australian varieties imported being brittle and of inferior grade.

During this period there was a notable revival of the supply of Russian asbestos, mostly short stock for shingles. There is evidence to show that these shipments are from stocks accumulated during the war time, and that little asbestos is being produced in Russia today. Prior to 1914 Russia provided the principal competition for Canadian asbestos in the German market.

A research conducted at the Technical High School in Munich, Germany, has disclosed the fact that the discoloration of lithopone-white pigments is due solely to the presence of the heavy metals (lead, antimony, etc.) as impurities. Lithopone made from pure barium and zinc compounds is absolutely unaffected by light.

It is not yet generally realized among domestic users that bituminous coal, which is objectionable on account of the smoke and gas evolved, can be converted into an ideal fuel, coke, in by-product coke-ovens.

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

## "Ottumwa" Hoists Built in Canada

This Hoist hauls a 15 Ton Load on a 45° Slope at 1600 ft. per minute. Drums 107" Dia. by 50" face. 1 1/4" Rope. Driven by 900 H.P. Motor Through Single Reduction Herringbone Gears. Clutches and Brakes Oil Operated.

One of several exclusive features of the "OTTUMWA" Hoist is the PROPORTIONAL PRESSURE CONTROL for power operated brakes. Successive positions of the hand levers give definite and increasing increments of braking effect. A simple and reliable device which effectively replaces the usual complicated gear with superior results. Has proved its worth on many installations.

# You Will Want a Copy For Your Desk

*Once the convenience and the time saving features of THE ELECTRICAL DIRECTORY OF CANADA are made known to you. A compact manual of reference which gives in concise, readily-obtained form the specific current information which an industrial executive frequently must have on short notice. This book of reference contains*

the directors, officers, executive personnel, capitalization, bonds and essential operations for every public utility of importance in the Dominion;

the local officers, equipment, current, voltage and lighting and power rates for each locality in the Dominion which enjoys electric service;

the firm name, address and, in many cases, the branch of the electrical business engaged in, of the better known electrical contractors and merchandizers throughout the Dominion; this section alone includes information on some 700 firms;

the officers, committee chairmen, general office address and place of meeting for all important associations serving the electrical and power industry.

# *Indispensable to The Purchasing Agent*

*THE ELECTRICAL DIRECTORY OF CANADA contains a wealth of the dependable information which is daily required by the purchasing agent. No buyer will be without a copy once he is aware of its usefulness. In addition to the features previously mentioned, it contains*

a complete trade directory of 350 pages listing the suppliers for almost every article of an electrical nature used in industry and in the household throughout the Dominion, comprising some 1,200 items of electrical apparatus, devices and supplies;

a large fund of concise information regarding manufacturers and distributors serving the electrical and power field; gives the names of the principal officers, the lines dealt in, the address of head and branch sales offices and, in many cases, the sales representatives.

# *Of Special Value to The Electrical Engineer*

*The Plant Superintendent, the Maintenance Engineer, the Electrical Foreman and every technical specialist or executive who has occasion to specify, order or define electrical products. Reference to THE ELECTRICAL DIRECTORY OF CANADA will do much towards accomplishing the elimination of inaccuracies, incompleteness and vagueness in correspondence and the issuing of requisitions.*

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.         | Value.      | Year.         | Value.       |
|---------------|-------------|---------------|--------------|
| 1891 .. . . . | \$4,705,672 | 1906 .. . . . | \$22,388,383 |
| 1896 .. . . . | 5,235,003   | 1911 .. . . . | 41,976,797   |
| 1901 .. . . . | 11,831,086  | 1916 .. . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

THOS. W. GIBSON,  
Deputy Minister of Mines,  
TORONTO, CANADA.

**FLEXIBLE AS A BELT—POSITIVE AS A GEAR—  
MORE EFFICIENT THAN EITHER**

**B**BETTER power transmission means more efficient and reliable operation of your equipment. That is just what the Link-Belt Silent Chain Drive can accomplish for you.

The drive runs in an oil-retaining, dust-proof casing—compact—conveniently located—safe. Re-

quires practically no attention. Where can you find a better means of transmitting power to your equipment, especially from a motor.

Let our experienced power transmission engineers show you what Link-Belt Silent Chain can accomplish in your mill.

## **CANADIAN LINK-BELT COMPANY, LTD.**

Wellington & Peter Sts., TORONTO

10 Gauvin Lane, MONTREAL

# **LINK-BELT**

## **SILENT CHAIN DRIVES**

# PROVINCE OF QUEBEC

## MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

**MINER'S CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is \$10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of \$10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of \$5 an acre for SUPERIOR METALS, and \$3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**HONORABLE J. E. PERRAULT,**

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

# BRITISH COLUMBIA

## The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, \$76,177,403; Lode Gold, \$105,557,977; Silver, \$55,259,485; Lead, \$48,330,575; Copper, \$166,393,488; Zinc, \$21,848,531; Coal and Coke, \$225,409,505; Building Stone, Brick Cement, etc., \$34,072,016; Miscellaneous Minerals, \$1,210,639; Making its mineral production to the end of 1920 show an

**Aggregate Value of \$734,259,619**

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive \$94,547,241; for five years, 1896-1900, \$57,605,967; for five years, 1901-1905, \$96,509,968; for five years, 1906-1910, \$125,534,474; for five years, 1911-1915, \$142,072,603; for the year 1916, \$42,290,462; for the year 1917, \$37,010,392; for the year 1918, \$41,782,474; for the year 1919, \$33,290,313; 1920, \$35,543,084; 1921, \$28,066,641.

**Production During last ten years, \$336,562,897**

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia.  
THE HON. THE MINISTER OF MINES.

### Let Us Help You Solve Your Flotation Problem

Flotation operators and engineers who have taken advantage of our offer to co-operate with them in determining the correct grade of Hercules Pine Oil for use in their plants are extremely satisfied with the results.

It has long been known that pine oil is the best frother so far brought to light and that it recovers more concentrate per ton of ore than any other reagent. The difficulty has been to get pine oil of uniform quality.

Hercules Pine Oil has solved that problem. It is produced under strict chemical control, which makes it possible to furnish it in unvarying shipments according to specifications.

Let us know your flotation problem. Our technical staff may be able to help you.

- Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.
- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars** relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**
- Summary Report.** The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memoir 108. The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

***USE HISCO BALLS***

"If quality counts use 'Hisco' Products" *Hisco Balls* are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to

Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.

Sizes 3, 4, 5 and 6 inch carried in stock.  
Special sizes from 6 inch up made to order.

*It behooves us [the Canadian Mining Institute], as the body most likely to be affected, to do what we can to put the work, not only of ourselves but of the profession at large, on the highest possible plane. —J. B. Porter — 1897*

### PLAIN SPEECH

In Mr. T. A. Rickard's paper, "The Duties and Privileges of Technical Journalism," reprinted in the February number of the "Monthly Bulletin" of the Canadian Institute of Mining and Metallurgy, there is a startlingly clear statement of the case against "subsidized journalism." Mr. Rickard uses that phrase to describe publications of technical societies that strive to take the place of independently published technical periodicals.

There is nothing equivocal in Mr. Rickard's attack and indictment. "The independent technical press in Canada and the United States is entitled, so long as it performs its duties efficiently and honorably, to be immune from commercial competition on the part of publications issued by Mining Institutes in the two countries... A paper more than 60 years old has gone out of business partly in consequence of the invasion of its field by the subsidized journalism of a social organization; to be specific, the 'Mining and Scientific Press,' founded in 1860, ceased publication in 1922 because, among other reasons, the American Institution of Mining and Metallurgical Engineers has chosen to engage in publishing a monthly magazine meant to cover the same field. Again, the 'Canadian Mining Journal' has been reduced to a mere simulacrum of itself by reason of the commercial competition established successfully by the monthly magazine issued by the Canadian Institute... You — the mining profession — are killing independent technical journalism for the sake of substituting something entirely different; you are developing a subsidized technical press controlled by a coterie."

Perhaps no one but T. A. Rickard could have written so poignantly on the subject. Strong his language is, but his facts and his logic are equally strong. His conclusions are incontrovertible.

Let us, like Mr. Rickard, be frank. Twenty-odd years ago, the late B. T. A. Bell, the founder of the "Canadian Mining Journal" (which began existence as the "Canadian Mining Review") also organized the Canadian Mining Institute. His publication was the official organ of the Institute and made the Institute's existence possible. For years Bell nursed the Institute through perilous illnesses. Mr. H. Mortimer-

Lamb, who succeeded Mr. Bell as editor of the "Review," became secretary of the Institute. When the "Review," under changed ownership, became the "Canadian Mining Journal," Mr. Lamb was for some years a highly valued contributor to the "Journal's" pages and those pages were always freely at the disposal of the Institute. Gradually, however, the scope and size of the Institute's "Monthly Bulletin" were increased. Gradually, also, it absorbed more and more of the Secretary's time to the exclusion of other highly important duties. The "Bulletin", from being merely a reprint of the Institute papers, now became a serious competitor in the field that had been exclusively the "Journal's". Inevitably the "Journal" suffered. Whilst we hardly agree with Mr. Rickard's cheerful asseveration that it is now "a mere simulacrum" of its former self, it is true that the "Journal" has been grievously handicapped by the competition gratuitously offered by the "Bulletin". The "Journal" is not given to complainings; but it has felt itself wounded in the house of its friends.

The culminating point has now been reached. Last year the Institute very nearly bankrupted itself by spending more than half its income on publications. Enforced retrenchment now necessitates the elimination of those sections of the "Bulletin" that mostly made it a competitor of the "Journal."

Consider now these facts. In its effort to enter the field of commercial journalism, a field already amply filled, the Institute has come close to wrecking itself. It has also severely restricted the usefulness of the publication that has been, and is, the recognized organ of the mineral industries of Canada. These have been the net results of a costly and ill-advised experiment.

At this point Mr. Rickard may again be effectively quoted: "Permit me to make another suggestion — applicable also as between your Institute and the 'Canadian Mining Journal': As there is now only one technical mining paper in the United States, why should it not set aside two or four pages gratuitously in each issue for the use of the secretary of the Institute?... It appears to me to be one way out of an intolerable position, and a step advantageous to both parties."

"The Canadian Mining Journal" recognizes in this suggestion a solution of the "impasse" that has existed. Such an arrangement will become mutually

and increasingly beneficial as time proceeds. And it is our strong conviction that this is the most direct road for the Institute to take towards solvency and efficiency. A definite offer of co-operation on these lines has been made to the Council of the Institute, and rejected. If a future occasion should warrant it, the offer will be renewed.

There is much work for the Institute to do. This work cannot be well done unless attacked with single-ness of purpose and concentration of effort. It cannot be done at all if the Institute permits its energies to be dissipated in directions that are foreign to the national purposes for which it was founded.

### THE PROSPECTOR'S PROGRESS

The mining engineer in Canada is developing rapidly a regard for his fellow-worker, the prospector. It is well that this is so, for their interests are intimately connected; in fact they are inseparable. The prospector of today has earned the regard of the engineer by reason of the immense advance he has made during recent years in his methods of prospecting. Just at present he is struggling with some measure of success to fit himself better into the economic organization of the mining industry; that is he is learning to demand less cash from the man who will develop his raw prospect, and is trying hard to be satisfied with a further grubstake and a share in the mine-to-be.

How has the mining engineer charged with the responsibility of examining the prospector's find responded to the call for coöperation? Not so well as the prospector, we fear. There is still a prevalent tendency to expect a ready-made mine, a thing no prospector can provide. Fortunately here, again, a spirit of progress is in the air, and the reasonable attitude of a small number of examining engineers who have made an outstanding success of their work is educating the remainder to the necessity for active coöperation with the prospector. As has been pointed out frequently, sound advice and judicious encouragement will often stimulate the prospector to effort that will put his property "over the hump." Such assistance on the part of the engineer costs him nothing and is bound to be of benefit to himself as well as the prospector in the long run. A number of our geologists in the public employ do this service to the prospectors systematically, and although they do not benefit by a dollar's worth in the result, the occasional public acknowledgement of the practical benefit of their services must warm the cockles of their hearts.

The growing appreciation of the work of the Canadian prospector might well be reflected in the Canadian Institute of Mining and Metallurgy, where as yet he has received scant attention. There is no reason why the trained prospector should not take his place

alongside the trained mining engineer in the Institute's deliberations on behalf of the mining industry. If prospectors were more adequately represented in the Institute some of the pressing problems connected with their work, and of vital importance to the mining industry, might receive the attention they deserve at the hands of the Institute.

We bespeak for Canadian prospectors the attention and consideration they have earned and deserve.

### DANGER THREATENS IN SYDNEY

The relation of workers and employers in Sydney, Nova Scotia, is in desperate need of re-adjustment. The recent strike at the steel plant is merely a symptom of a disease that is deep-seated and has spread throughout the larger part of the body of workmen there present. This is what our correspondent says: "Things do not look at all encouraging at the steel plant. The men are in a determined mood. They say their wages are too low and that they must have recognition of their union. A trial of strength has given them a false opinion of their powers and it may be that nothing but a strike will settle things. I cannot think that it will spread to the collieries, as the miners are under contract. However, with the Reds as leaders, anything might happen."

A shrewd and disinterested resident of Sydney writes as follows: "The unrest that I have often spoken of in my correspondence culminated last week in a strike, about which you have full particulars. This caused a loss of at least \$60,000, in wages and probably a much larger loss than that in damage to property, owing to the Steel Company not being able to care for their furnaces, etc., sufficiently quickly. There were no acts of violence, but there were many acts of intimidation; that is, there were large numbers of men at different points acting as pickets that prevented men going to work, who tried to go but did not force their point as they were not sufficiently enthusiastic about going to work to force the issue. Not only did this apply to workmen, but also to stenographers and other girls employed in the company's offices; also to ordinary citizens who were going to the plant in connection with their business, and not to work, and very especially delivery teams that were about to deliver various classes of merchandise to the plant. In this way, law and order were given up and the power and wish of the strikers used instead.

"The matter is now finished, but apparently neither the men nor the company are any more amicably disposed toward each other than before. Unless some rapprochement is made between the parties (whether by the church, the government, or the public, or even themselves) the unrest is still present, and may break out to a much greater extent and with greater violence at any time. This uncertainty and lack of confidence hurts the community from one end to the other."

The anti-social utterances of the Red leader, McLachlan, at the Labour Temple in Toronto on Sunday of this week discloses clearly the immediate cause of the unrest in Sydney. McLachlan and his coterie of brother Bolsheviks preach unqualified revolution in order to attain to ends that are economically as well as socially impossible in this country at this time. We are convinced that this fire-brand labour leader has gone far beyond the bounds of free speech and that he is guilty of license in the eyes of the law.

To prosecute and imprison these misguided Reds and let the case for law and order rest there would, however, be a senseless attempt to right the situation. The Red agitation is merely a symptom of a disease that is deep-seated. The workmen of Cape Breton are a level-headed lot, and were it not for some well-founded sense of injustice that is poisoning their systems, the deadly germs of extremist agitation could not find lodgement.

Last week there appeared in these pages an article describing the attempts of the Colorado Fuel and Iron Company to adjust on an equitable and lasting basis their relations with their employees. We hope that it will require no such catastrophe as occurred in Colorado in 1913 to force in Nova Scotia a similar determined attempt to solve the labour problem. It is interesting to note, by the way, that our present Premier, MacKenzie King, was largely instrumental in formulating the plan now governing the labour relations of the Colorado Fuel and Iron Company. The plan has been in successful operation since 1915.

Where the employees of a large company are scattered in comparatively small units through the country, as for instance is the case of the Imperial Oil Company or the Bell Telephone Company, a solution of the labour problem is comparatively easy to find. Both these companies have succeeded in enlisting the active support and interest of their employees by offering them stock at advantageous rates. On December 31st last 4,318 employees of the Bell Telephone Company were shareholders — over half the total number of the Company's shareholders. The Joint Industrial Council plan is giving excellent satisfaction with the Imperial Oil Company. In both cases the spirit of co-operation has resulted in sick benefits and pensions for employees, and the mutual good-will pays on every score.

Where the workers are segregated in large numbers and are without the leavening influence of a large proportion of workers in other occupations, as at Sydney, the problem is more difficult, but assuredly it is capable of solution. The British Empire Steel Corporation with commendable zeal have set about the task of improving the material surroundings of their employees. First-aid stations, bath houses, safety precautions and cleanliness and order in mine and surface plant have had much attention and a considerable ex-

penditure, and lately the housing problem has been tackled in a thoroughgoing way. We have yet to learn that the personal, human relations have been studied with similar care, and certainly no adequate measures have been adopted to enlist the coöperation of the Sydney workmen.

The labour problem is now the most serious problem facing the British Empire Steel Corporation, Canada's largest and most important metallurgical undertaking. Unless the management of this corporation, from president downwards, takes prompt and effective measures to enlist the coöperation of their workmen in Sydney instead of creating antagonism as at present, the rising tide of dissatisfaction and revolution will overwhelm the industry and cause irreparable damage that will be a disgrace to themselves as well as to Canada.

### EDITORIAL NOTES

Next week we expect to give a resumé of the conference on research held last week in Ottawa, with an estimate of the results attained. Meantime we are able to print today the text of Dr. C. V. Corless' address before the conference, which is considered to be one of the outstanding items of the proceedings. It is a pleasure to be able to record the fact that one of the leaders in our mining industry is thus able to play a leading role in a nation-wide conference on research.

The miners of Sydney, Nova Scotia, have voted against a fifty percent increase in Union dues suggested by their leaders. Red rule may prove to be too expensive for thrifty Nova Scotians.

### "ST. SIMEON STYLITES"

I loaned me rifle to a guy;  
He said he'd treat it well—  
I **took** it back a week ago  
Just rusted plumb to h-ll.  
A feller blew into me shack  
And ast me for me axe;  
He bust his own and wanted mine  
To split his firewood stacks.  
I never seen that axe again,  
It was a good one too;  
But when you're lendin' that's the way  
It always ends for you.  
I loaned a man me name acrost  
A promissory note.  
The man fell down; I lost me name:  
The banker grabbed me goat.  
I'll never lend the loan of naught,  
And I'll not borry neither:  
I'll be the only bird on earth  
That damn well don't do either.

J. C. M.

# Hudson's Bay Bill

By TOM SAVILLE

We were in Montreal for "The Big Event". It was the evening of the opening day and already the Big Wigwam was filled to capacity — and already East and West had locked horns over the liveliest of issues, Institute Membership Policy. Strangely enough the battle cry of both sections was one and the same. The West had sent their ablest and best to give battle to the Secretary's proposals and as matters now stood, about the only advantage we of the East had was fighting them on our own ground.

We were having dinner, members from the North, South East and West, our battles for the day were over and we were boys again, glad of the opportunity of enjoying each other's company in all good fellowship.

Nicholson, a Western member, and myself were discussing the mysterious disappearance of Lionel Mortimer. Mortimer had been the guiding genius of the Western faction and had come east about a year ago and had taken charge as examining engineer for the Pioneer Exploration Co. He had already been successful in landing several interesting looking properties and was going strong when in the fall he ran across a prospector known in the North as Hudson's Bay Bill, who shows him some good looking kaolin he has run across down on the Missinabi. They left, just the two of them, to make an examination, expecting to be out before the freeze up, and that's the last we heard tell of them. Search parties have been sent out, but have returned with no news. The prospectors still maintain that Hudson's Bay Bill will show up yet, unless he has cashed in from sickness, as he is a regular wizard of the woods and sure knows the way to look after himself. However, it looks like "Good night" to the both of them.

While we are lamenting his loss a boy hands Nicholson a telegram, which he read aloud. "Have arrived Cochrane, Ontario, hale and hearty. Hope to meet you opening day, Big Event, Montreal. Lionel Mortimer." And while we are cheering the good news, in walk Mortimer himself looking the same as his telegram states, hale and hearty. We sure give him a great old shake and he is soon the centre of an eager crowd expectantly waiting to hear how he escaped "the relentless clutches of the inhospitable North." Mortimer is quick to sense this, and after some more chairs are brought in he begins.

"Late last fall, a prospector known as Hudson's Bay Bill met me on Big Appitipe and showed me some samples of good looking kaolin which he tells me he got on a river running into the Missinabi, Kawa-pa-ska-ka-ming. Having heard on good authority that an extension of the P. & T. would shortly run through that country, I decided to look it over before the freeze up. I asked Hudson's Bay Bill what he thought about getting out before the freeze up, and he says we can make it but it will keep us a-humping. I was in great shape after my simmer's work which had kept me on the trail almost continuously, and I could see that this prospector was trail hardened too. So we got an outfit from the H. B. Co. and took to the river down stream and outside of running some ugly looking rapids the trip to the discovery was uneventful.

"I examined the outcrop and Hudson's Bay Bill informs me there is another exposure to the West, but that we had better be getting south as the geese were on their flight and that we had better follow them. But the weather was fine and after coming this far I thought I would see everything possible. So we made a cache of our outfit, taking only a light tarpaulin for a lean to at night, and only the barest necessities in the way of provisions, intending to make a dash for it. We made it all right, took some samples for analysis and was within a short distance of our cache when it started to storm, snow and blow, which made very slippery walking.

"We were working our way though a windfall and you know what that means, we were off the ground half the time. Hudson's Bay Bill was a little ahead of me, walking like a bear—in-toes along a down tree—and I was just wishing I had that accomplishment myself, —when, Bingo, I slip off and down between a couple of logs — and break my leg.

"We both realize we are up against the real thing—frozen in without an outfit; but it don't seem to worry Hudson's Bay Bill, who first packs me to a good place to make permanent camp — wood, water and protection from the north wind, which, of course, means facing south. He soon has me on a thick spruce bough bed alongside the fire and sheltered from the storm by the "puckwan" or lean-to and is working over my leg which he sets and puts in a plaster cast made out of kaolin and rabbit hair, and after he makes me as comfortable as possible starts to split some jack pine to build a camboose, right over me and the next day he has the roof on and I am laying alongside a cheerful fire inside one of the neatest little camps I have ever seen.

"It was still storming, but Bill had got the best in the first round. I could see it was going to be a battle, but I had faith in Bill's ability to win out. Well it's a long story, but an interesting one (the details of which you will get in my paper 'Prospectors at Close Range') of how we lived off the country and lived good without a gun; of how we made winter clothes and footwear from the skins of animals he caught and tanned; the snowshoes and toboggan Bill made with home-made tools; and best of all how in those long winter evenings while he would be sewing or making some useful article he would make me forget the pain and misfortune of being confined to camp, with his stories and his fine sense of humor.

"I can assure you I had an excellent opportunity of getting 'a close up' of the Prospector. I learnt that Hudson's Bay Bill was not an exception, but one of many red-blooded men who are playing the 'Big Game'. I learnt that the majority of them are in the 'Game' not because it is the best paying one, but because it affords better opportunities for service to their fellowmen. I saw prospectors studying Dana and Miller by the light of their campfires. I have met prospectors who had travelled for days to hear Dr. Goodwin tell the 'Big Story' to his prospectors' classes.

"Now, gentlemen, these are the men whose efforts to improve themselves I was working against in the

# Bulletin and Journal

## CORRESPONDENCE RELATING TO A PROPOSAL TO COMBINE THESE PUBLICATIONS

*In November last Mr. J. J. Harpell, managing director of the company that publishes the "Canadian Mining Journal", offered to the Canadian Institute of Mining and Metallurgy the use, without cost and without restriction other than that which binds both Institute and "Journal" in the service of the mining industry, of a sufficient number of pages in the weekly issues to publish the technical papers and announcements and whatever other material the Institute deemed advisable. The following letters from Mr. MacKenzie, on behalf of the Council of the Institute, and from Mr. Harpell are self-explanatory after this introductory note.*

Montreal, December 12th, 1922

J. J. Harpell, Esq.,  
Industrial & Educational Publishing Company,  
Gardenvale, Que.

Dear Mr. Harpell,

The proposal for combining the "Monthly Bulletin" of the Institute with the "Canadian Mining Journal" was laid before the Council of the Institute on December 8th., and, after the matter had been very carefully reviewed and considered from all angles, Council decided that it would not be in the best interests of the Institute to carry out the proposed publishing combination. I might add that the whole matter has been carefully considered by the Council at large, and also by the Council Meeting on November 17th, in Vancouver, B.C., the consensus of opinion being that the Institute would lose its present contact with Branches and individual members through the adoption of the scheme which we have been discussing.

Notwithstanding the fact that we cannot get together on this proposition, for the present at least, I feel confident that the friendly relations which have previously existed between the "Bulletin" of the Institute and the "Canadian Mining Journal" will continue indefinitely.

Yours faithfully,

GEO. C. MACKENZIE,  
Secretary-Treasurer.

Gardenvale, January 8th, 1923.

Geo. C. MacKenzie, Esq.,  
Secretary-Treasurer,  
Canadian Institute of Mining & Metallurgy,  
603 Drummond Building, Montreal.

Dear Mr. MacKenzie:—

Your letter of the 12th ult. reached here during my absence and since my return I have delayed answering it until I had an opportunity, which you were good enough to give me on Friday, of examining the minutes of the last meetings of the council.

I am sorry that the proposal to combine the "Bulletin" of the Institute with the "Canadian Mining Journal" has been turned down. The Canadian mining industry is not large enough to support two jour-

nals, and the effort to force two upon it has simply resulted in weakening the service that might be given by one and in piling up a liability against the Institute of Mining and Metallurgy which has undertaken to finance the other.

I wonder how many members of the Institute are aware of the fact that your total expenditure for 1922 has been over \$36,000 and your total revenue less than \$25,000 and that every cent of this heavy deficit, namely over \$12,000, has been occasioned by your effort to build up a competitive Canadian mining publication? In one year you have spent the greater part of the surplus built up at great pains during several years by your predecessor and it will require less than one more year of such expenditure to put the Canadian Institute of Mining and Metallurgy into bankruptcy.

When this serious condition was discovered by the members of your council a few months ago it created something of a panic that occasioned negotiations with us looking to the amalgamation of the "Bulletin" with the "Mining Journal." What has happened in the meantime? The minutes of the last meeting of the council tell the tale. You presented a budget, just as you did last year, supported by rosy prognostications of what you can accomplish in another 12 months and have succeeded in persuading the few members that were present to adopt your programme of promises and hopes of an inexperienced and heretofore unsuccessful publisher. You have persuaded them to authorize a contract for printing amounting to \$6,000 which any shrewd buyer of printing could get for \$3,000 at the present time. Last year it took \$36,000 to meet your bills. In your budget of 1923 you say you can keep the expenses of the Institute under \$21,000 and you immediately start on a road of greater extravagance and unnecessary expenditure than you did in 1922.

Mac., you have either lost your senses or you are out to wreck the Institute. The members should know the facts and be given an opportunity to have a say in what is as much their affair as it is yours and the half dozen or so members of the council that you gather in occasionally to endorse your programme.

Why have the minutes of your council not been published in the "Bulletin," which circulates only among the members? Why? Because they would raise a storm that could not be weathered by the present management. But notwithstanding the friendly, and even close personal relations that exist between the writer and many of those who may be affected, I consider it my duty, as a member of the Institute of many year's standing, to force all cards to be laid on the table, to give every member a full and complete knowledge of the facts so that at the next annual meeting they may deal with the whole matter as they see fit.

I am, therefore, writing this reply to yours of the 12th ult. with the intention of publishing both in the "Canadian Mining Journal" and I will be very glad to publish at the same time any reply you may feel you would like to make to this letter. You are free to publish my letters in any publication you wish.

I know you feel that this matter, if it is to be made

---

west — the men I was trying to exclude from a source of inspiration that rightfully belongs to them,—and I have now learnt is the birthright of all legitimate members of the mining family — full membership in the Canadian Institute of Mining and Metallurgy."

public, should be continued to the readers of the "Bulletin". But it is not only of interest to the members of the Institute but of vital importance to every member of the Canadian mining industry. Judging from the long lists of cancelled memberships you have shown me I am satisfied that there are many ex-members of the Institute who are just as anxious that the Institute be reestablished along the lines of its former usefulness as are present members — probably more so.

The "Bulletin", being the organ of the Institute, ~~is read only by present members~~. The "Mining Journal", being the recognized organ of the Canadian mining industry is or may be read by everyone interested in the welfare of the industry, including not only all present members of the Institute but ex-members and prospective members as well.

It is the duty of the secretary of all public and semi-public organizations to be guided in his course of action by fundamental principles, generally acceptable to the constituency he is appointed to serve, and I am going to open this discussion by calling to your attention how completely your course of action violates an important principle generally, if not unanimously accepted by the Canadian mining industry. The mining industry of this country has always been opposed to any interference with private ownership — it has stood for intelligent individualism. But the effort you have been making during the last year to displace the "Canadian Mining Journal" with the "Bulletin" is directly opposed to this principle. How would any mine owner feel if the Institute of which he was a member began to operate a competing mine with Institute funds? The men who invested their money to establish the "Canadian Mining Journal" are, (or were up to the time of their death) all members of the Canadian Institute of Mining and Metallurgy. They are as follows:

Alexander Longwell, Toronto.  
Dr. Milton L. Hersey, Montreal.  
J. B. Tyrrell, Toronto.  
Prof. S. F. Kirkpatrick, Ottawa.  
Prof. J. C. Gwillim (now the estate of)  
Eugene Coste, Calgary.  
L. H. Timmins, Montreal.  
Dr. James Douglas (now the estate of), New York.  
J. J. Harpell, Gardenvale, Que.

In investing their money in this venture each of these men was influenced more by a desire to keep the old "Mining Review" from being purchased by an American company and to provide a creditable Canadian mining publication than by any opportunity it offered for investment. As a matter of fact the "Canadian Mining Journal," by itself, has never proved a profitable venture. The above mentioned shareholders, who still have their original investment, can tell you that they did not receive regular dividends until after the company owning the "Mining Journal" went into the printing business.

So long as the "Bulletin" was no more than a bulletin it did not compete with the "Canadian Mining Journal", but during the last year the "Bulletin" has been, in all essential particulars, a magazine with an editor and an advertising solicitor, and the Institute by publishing the bulletin, at heavy financial loss, has really devoted its greatest effort and energies to the business of publishing which is not, I think you will admit, the most important duty of the Institute.

Even though you should succeed in accomplishing your purpose what will you have to show for the money spent? Nothing more than a monthly bulletin — a house organ that circulates only amongst the members of the Institute. Because of this limitation it can never exercise much, if any, influence in attracting attention to the mineral resources of the country nor can it be of service to the 70,000 workers in the industry beyond the 1,000 or so who are members of the Institute.

The Canadian Institute of Mining and Metallurgy is the only industrial society in Canada that receives a Federal subsidy. If the government knew that this subsidy was being used to compete with a private industrial undertaking it is doubtful whether it would be continued. If the Institute wishes to go into the publishing business it has no right to a Federal subsidy. I might have hesitated to so express my feelings on this matter were it not for the opinion you voiced on Friday, namely that this subsidy had frequently deterred the Institute from being more aggressive in their dealings with the Federal Government when the interests of the Institute demanded.

This opinion removes an obstacle that deterred me from opening up the whole matter a year ago when you asked the Institute for authority to embark on your publishing enterprise. But now that you have had a whole year's experience without getting any nearer your goal than you were when you started, the members of the Institute should at least know what it has cost them and have an opportunity to consider whether or not they wish to continue to finance your publishing enterprise. They should also know that for many years the Industrial & Educational Publishing Company, which is the owner and publisher of the "Canadian Mining Journal", printed the "Bulletin" for the revenue from the advertisements it carried which was as follows:—

|               |            |
|---------------|------------|
| 1918 .. . . . | \$1,615.18 |
| 1919 .. . . . | 1,584.52   |
| 1920 .. . . . | 2,024.65   |

On this basis, of course, there was a loss of from \$1,000 to \$2,000 a year which was absorbed by the Industrial & Educational Publishing Company, Ltd. In 1921 you had complete charge of the advertising and the Industrial & Educational Publishing Company did the printing for the Institute at a total cost of \$3,407.87.

In 1922 you took the printing of the "Bulletin" away from the Industrial & Educational Publishing Company, Ltd., and paid from two to three times what it cost in 1921, notwithstanding that printing costs in 1922 were very much lower than during any of the four preceding years. Your revenue from advertising was about the same as it had been during the previous year notwithstanding the strenuous and expensive effort you made to increase it. The deficit on mechanical costs alone in 1922 was unnecessarily high.

I should like to have the members of the Institute compare the "Bulletins" for the four years during which the Industrial & Educational Publishing Company printed them with those of 1922 and say if the publication under your management is worth from three to five times what it was during any one of the four previous years. The only apparent difference is one of type face which, of course, does not mean a dif-

ference in cost. That is simply a matter of taste and it is doubtful if the change you have made in this respect can be considered in the nature of an improvement. Then you must not forget that the Industrial & Educational Publishing Company has built up one of the largest printing businesses in Canada within a comparatively few years. This could only be done by giving service and a quality of printing at least equal to that of its competitors.

I do not quite understand why you should be so anxious to spend so much of your time on an effort to displace the "Mining Journal" with a publication financed by the Institute. It is certainly not because there are lacking suitable activities for the secretary of the Institute. The fact is that the Institute is not now a vital force in the industrial life of the country as it should be. During the last few years there have been many occasions when the interests of the mining industry demanded the attention of some representative on freight rates, tariff classifications, and so forth and on each occasion the Institute remained unrepresented, although all the other important organizations had representatives present. By tariff classifications I mean the proper classifying of mine products for freight schedules. When a shipper receives his freight bill he has no power to change the class in which he finds the commodity placed from a given point of shipment no matter how unjust such classification may be. This is a technical matter of much importance to the industry and should be carefully watched and studied by the secretary of the Canadian Institute of Mining & Metallurgy.

A dozen activities could be mentioned that could better occupy the secretary's attention than the publishing of a magazine. For instance, there is the training and general aid to prospectors which has never yet been undertaken seriously in Canada. It is the "Canadian Mining Journal" and not the Institute that now has this undertaking under way though it is more properly the concern of the Institute and any surplus which the Institute may have should be spent upon work of this kind.

But the above mentioned are not the only developments of vital moment to the Institute arising out of your publishing enterprise. In your desire to corral manuscript for your "Bulletin" to the exclusion of privately owned mining publications, you prepared and had passed at the last meeting of the council, a minute which amounts to a vote of censure of Mr. T. A. Rickard for allowing the "Engineering & Mining Journal-Press" to publish the paper he read at the western meeting of the Institute at Vancouver before it appeared in the "Bulletin." If your interests in the welfare of the Canadian mining industry transcended your desire for the aggrandizement of your "Bulletin" you would have been glad of any attention that the "Engineering & Mining Journal-Press" gave the Vancouver meeting and Mr. Rickard's paper. You certainly must know that if a weekly mining publication had to wait for a month or more until Mr. Rickard's paper appeared in your "Bulletin", little or no attention would be given to it, and the Canadian mining industry and the Vancouver meeting would be the losers thereby.

If your heart had not been so centred in the "Bulletin" you would have recognized in a more fitting manner the courtesy Mr. Rickard did the Vancouver meeting instead of taking a course that must neces-

sarily be resented by his hosts, the Western members of the Institute. You surely must have known that if your desire for prior publication had been made a condition of Mr. Rickard's presentation of his paper at the Vancouver meeting he would hardly have accepted the invitation in view of his experience with the "Bulletin" of the American Institute of Mining and Metallurgy. When the council of the Institute could not afford to send you, or any other representative to the Vancouver meeting because your expenditure on the "Bulletin" had depleted the treasury, you should have refrained from creating an awkward situation for those who did go.

According to the records of the last meeting of the council your solicitude for the "Bulletin" has created a situation making it difficult for the Nova Scotia Mining Society to continue the good relations with the Institute established by your predecessor, and under the circumstances you should have avoided a course likely to alienate another important section.

The minutes of the last meeting of the council disclose another action of far reaching consequence to the industry. I refer to the acceptance of a thousand dollar donation from a large mining company and to a minute calculated to politely advise other mining companies that the hand of the Canadian Institute of Mining and Metallurgy is out for further gifts. Membership in the Institute is no longer of equal value and serious misunderstandings are bound to arise if this course of action is adopted by the Institute. On all these questions the members should have full information.

Through the columns of the "Bulletin", or in some other way, the members should be supplied with a full financial statement of each of the five years preceding December 31st 1922 together with an outline of the financial requirements for 1923. This statement should disclose the amount of the reserve at the end of each year. Each member should be supplied with a copy of the minutes of the last two or three meetings of the council of the Institute. There is no reason why these minutes should not be published regularly.

I make these suggestions believing that your frantic effort to continue the publication of the "Bulletin" is fraught with the greatest danger to the Institute. It is calculated to wreck the Institute and it will not take many more months as things are going now.

Before the Institute embarked upon its publishing enterprise it did a valuable work for one of the country's most important industries. There is still much good work for it to do and it is the duty of every person who has the best interests of Canadian mining at heart to save the Institute.

Yours very truly,

J. J. HARPELL.

Montreal, January 31st, 1923.

Mr. J. J. Harpell,  
Garden City Press,  
Gardenvale, P.Q.

Dear Mr. Harpell:—

Your communication of January 8th on the subject of Institute matters was laid before Council on January 17th and I have been instructed to write to you as follows:

(1) You state that at the end of 1921 Council took away from your Company the printing of the monthly "Bulletin"

At the end of 1921, your Company, among a number

of others, was asked to submit tenders for the printing of the "Bulletin" and the "Transactions" for the year 1922 notwithstanding the fact that you had, during the year 1921, given the Institute to understand that at the termination of your 1921 contract you did not desire to renew the same. You did tender for the "Transactions" but did not tender for the "Bulletin" and your failure to do so resulted in Council placing the printing contract with another company. Having ignored Council's request for your tender you are hardly in a position to state that the contract was taken away from you.

(2) You state that during the past year Council has published the "Bulletin" with the idea of displacing the "Mining Journal" and you assert that this competition was characterised and inaugurated with the appointment of a "Bulletin" editor and advertising solicitor.

You are reminded that the "Bulletin" has always possessed an editor and an advertising solicitor. Prior to 1921 the editor was the Secretary-Treasurer of the Institute and while at times paid advertising solicitors were employed the most active agent has always been the Secretary-Treasurer. Commencing with 1921 the editorial and secretarial duties of the Institute was separated in order that the Secretary-Treasurer could devote his whole time to secretarial duties and throughout 1921 and 1922 a paid advertising solicitor was not employed.

You fail to specify in what manner the "Bulletin" has competed directly with the "Journal" and should you care to pursue this subject further Council would be glad to be enlightened. In the meantime, you are referred to two editorials in the "Bulletin" issues of November and December 1921 on pages 947 and 1031 respectively, in which you will find the matter thoroughly covered.

(3) You refer to the present financial condition of the Institute, insinuating that this condition has been brought about suddenly. You also state that Council having recently discovered this situation approached your Company with a proposal to combine the "Bulletin" with the "Mining Journal."

If you had read the report of Council published in the February Bulletin 1921 you could have ascertained that Council had, as early as the fall of 1920, anticipated financial deficits for several years in advance and had fully explained the reasons for these expected deficits. You are, moreover, advised that Institute finances were repeatedly mentioned in articles that appeared in the monthly "Bulletins" throughout 1921 and 1922. Council would refer you particularly to the February, March and November Bulletins of 1921 and to the February, May, October and November Bulletins of 1922. Council would remind you that the proposal to combine the "Bulletin" and the "Mining Journal" originated with yourself and not with Council, nor were you ever approached on this subject by the present Council. Council were favorably disposed toward your proposal until it was shown conclusively that the most economical course to pursue was to continue the publication, in limited form, of the "Monthly Bulletin". This decision was made only after the whole question of Institute finances had been carefully reviewed by meetings of Council in Vancouver and Montreal.

(4) You ask why the minutes of Council have not been published in the "Bulletin."

Council would refer you to the procedure of the Institute for many years which contains no precedent for the adoption of your suggestion. Minutes of Council are always open to members at Headquarters and any member distant from Headquarters can see copies of these minutes on application to their representative Councillors. Furthermore, Council does not believe that anything would be gained by printing its minutes in the "Monthly Bulletin." All the forty members of Council are regularly supplied with copies of the minutes. These members are scattered across the country from Halifax to Vancouver and being constantly in touch with branch organizations it is recognized and accepted that distant members of Council will bring to the attention of branch executives anything in the minutes that requires their attention.

(5) You refer to a recent minute of Council recording Council's appreciation of cash donations to the Institute from individuals and corporations and you charge that in accepting such donations Council has established a practise that will affect the quality of membership.

Council would remind you of the established practise of the Institution of Mining and Metallurgy of Great Britain which has, in recognition of its services to industries, accepted on many occasions cash donations from individuals and corporations without injury to the quality of its membership.

(6) Your reference to a minute of Council covering the matter of Mr. T. A. Rickard's discourtesy to the Institute has been duly noted.

When Mr. Rickard consented to present a paper to the Institute he was fully conversant with the long established precedent requiring that such contributions, as a matter of ordinary courtesy, should first be placed at the disposal of the Institute. However, Council has, at the request of the British Columbia Division, re-considered this matter because it is probable that Mr. Rickard may have been unaware of Article 50 in the Institute By-laws. Council has therefore consented to the printing of Mr. Rickard's paper in the February issue of the "Bulletin."

Yours faithfully,

GEO. C. MACKENZIE,

Secretary-Treasurer.

## SYMPOSIUM ON FUEL

The outstanding feature of the technical sessions of the Canadian Institute of Mining and Metallurgy in Montreal next week will be, of course, the symposium on fuel. The papers on fuel have been prepared by the most competent authorities it has been possible to obtain, and their conclusions are worth the serious attention of all connected with the fuel problem — which includes the majority of Canadians. If the discussion of these papers is of corresponding importance, the Institute will have rendered Canada a notable service at its Annual General Meeting for 1923.

By reason of the virtual cessation of coal production in the Ruhr coal district, coal shipments from England and Scotland to both France and Germany have been increased to a marked extent, and prices have gone up.

## IN CONNECTION WITH THE MOND NICKEL COMPANY'S OPERATIONS

By C. V. CORLESS\*\*

### Outline of Operations

Since there may be some present who have only a very general knowledge of the mining companies operating in Northern Ontario, I will preface my remarks on research by such general statements regarding the Mond Nickel Company's operations as may throw light on later references to these.

The Mond Nickel Company, with head office in London, England, is the second largest producer of nickel in existence. It operates a number of mines and a reduction plant in the Sudbury District; refineries in the United Kingdom; a rolling-mill for nickel and one for nickel alloys, together with some other allied plants, in Birmingham, England; and has an interest in a rolling-mill in Clearfield, Pennsylvania.

All the ores produced in the Sudbury nickel area are sulphides of nickel, copper and iron (known technically as pentlandite, chalcopyrite and pyrrhotite), mixed with varying amounts of rock matter, and containing minute quantities of the precious metals and rare metals of the platinum group.

The Company's reduction plant, which is a few miles east of Sudbury, at Coniston, on the Canadian Pacific and Canadian National Railways, consists of a smelter, a sintering plant, and a concentrating mill. The final product of this reduction plant is bessemer matte, containing over 80 per cent. of nickel and copper, 14 or 15 per cent. of sulphur, a varying percentage of oxygen, a few tenths of a per cent. of iron, and small amounts of precious and rare metals, much too small to be expressed significantly in percentages.

This bessemer matte is shipped to the Company's refinery at Clydach in the Swansea Valley of South Wales, an important metallurgical center. Here the nickel and copper are separated, the former being refined by the carbonyl or Mond process which yields the purest nickel sold (99.8 to 99.9 per cent. nickel) and the latter being sold as copper sulphate, chiefly as an insecticide and fungicide for use in the vineyards of Southern Europe. The residues from this refining process, containing the minute proportions of the precious metals, (gold and silver) and of the rare metals of the platinum group (platinum, palladium, iridium, rhodium and ruthenium) are separated and refined at the Company's plant in London.

### Uses of Nickel

As is well known, nickel finds a very wide market as an alloying metal, chiefly with steel, but also with copper, chromium, manganese, and a number of other metals. Owing to the unique and valuable properties of nickel, it is finding wide uses in the manufacture of containers, utensils, piping, wire, machinery parts, scientific and industrial apparatus, etc., where its peculiar combination of properties, viz., great strength, capacity for receiving and retaining a high polish, great resistance to corrosion, abrasion and oxidation, or other special qualities, are required. It is also used extensively in electroplating, for coinage purposes, and as a

catalyst in certain reactions in industrial chemistry, besides having a large number of miscellaneous uses.

The Company has spent and is spending large sums of money in studying the physical and chemical properties, in investigating the best methods of manufacture, and in searching out the widest and most suitable fields for use, of nickel and its alloys. Some of these investigations are carried out at the plants in Birmingham and Clearfield already mentioned.

### Use of Research in Connection with Ordinary Operations

It perhaps need hardly be said that each of the plants mentioned has its chemical laboratory. The laboratory is the handmaid of every metallurgical process from the milling and smelting of the ore, through the various steps in further reduction and refining of the metals, and onward into the manufacture of the metal into sheets, bars, wire, tubes, etc., whether these are of pure nickel or of nickel alloys. In investigating these final forms, so as best to adapt the metal or alloy to the particular use for which it is intended, frequent physical tests are applied; for example, tests for electrical resistance, tensile strength, brinell hardness, etc. These tests have to be correlated with both the chemical composition of the metal and the physical and mechanical treatment the metal has received. Half a dozen or more chemical laboratories, with some of the less expensive apparatus for physical testing, are in constant use at every stage between mine and consumer. Some of the larger physical and mechanical tests, which are used less frequently, requiring very costly apparatus, are made, when advisable, in University or other similar laboratories for testing such materials.

It is not the purpose of a brief non-technical paper, such as the present, to do more than to give a broad outline of the place of research in a mining and metallurgical industry and to indicate the indispensability of accurate and systematic chemical analysis, physical testing, observation, recording of data, and of correlation and drawing of reliable conclusions from a close study of them, which, with the applied scientist, is one form of research. Without this continuous, painstaking, systematic, detailed following up of daily metallurgical operation; without the most careful study and correlation of the masses of accurate data by scientifically trained men who devote their time to this work; without the drawing of conclusions based on these studies, which sometimes extend over many months; and unless these studies result in decisions to make operating experiments, frequently on a full working scale; there would be but little metallurgical progress.

### Special Industrial Research — Origin of the Mond or Carbonyl Process

But there is a further important aspect of industrial research, well illustrated by the early development of the refining process used by the Mond Nickel Company, which is known as the Mond or carbonyl process for refining nickel. The story of this development is probably familiar to any metallurgists present. Since it may not be so well known by others, I will briefly outline it.

In laboratories having as their chief aim the appli-

\* Address given before Research Conference, London, Feb. 21st.

\*\* Director and Manager of The Mond Nickel Company, Ltd.

ration of scientific discoveries to industry, quite frequently important discoveries are made in pure science. Research men in such laboratories keep abreast of advances in science just as do others engaged in research work merely for the advancement of knowledge. When such purely scientific discoveries are made, after verification, they usually find their way through the ordinary channels to the general stores of scientific knowledge. Sometimes unexpected phenomena are observed which it may be necessary merely to note "en passant". These phenomena may form the starting point of fresh researches into their scientific meaning and into their practical application, if any.

It was thus in Dr. Mond's laboratory in England that a scientific discovery was made which formed the starting point of the carbonyl process for refining nickel. A mixture of hydrogen and carbon was being passed over heated, finely divided nickel in order to remove the carbon monoxide. To obviate danger from the poisonous monoxide, the escaping gas was ignited. As the apparatus cooled it was observed that the burning of the escaping gas produced a luminous flame which deposited a film of nickel on cold porcelain, very similar in appearance to the well-known arsenic mirror used as a test for the latter metal. A test showed this deposit to be pure nickel and further investigation revealed the existence of a hitherto unknown compound of nickel and carbon monoxide,  $\text{Ni}(\text{CO})_4$ , which received the name nickel carbonyl. This compound is formed by passing carbon monoxide over metallic nickel at about  $50^\circ \text{C}$ . but is again completely decomposed into nickel and carbon monoxide when heated to  $150^\circ \text{C}$ . or higher.

These are scientific facts. As such they merely increased the sum of human knowledge. They were discovered incidentally in the course of research carried on with ultimate industrial aim. But in the fertile brains of Dr. Mond and Dr. Langer — both men gifted with scientific imagination and indomitable determination, the one having already won by previous investigations and applications of science to industry practically unlimited capital which enabled him to back the other, who had deep scientific insight combined with great originality and inventive genius — in this fertile soil, these scientific facts proved to be seeds that quickly germinated. But though the germination was quick, full development required much time, faith, courage and will. There followed a period of more than ten years of patient research, invention and construction, during which boundless faith, a faith which was literally "the evidence of things not seen" except in scientific imagination, was the impelling force. Finally an ore body was bought in the Sudbury District, three thousand miles distant, at a time when the future of the district was by no means assured; a mine was developed; a smelter built; in order to test the commercial value of the new process. This was nearly twenty-five years ago. I need only add that since then ample ore reserves have been secured, a new and more adequate reduction plant has been built, and the carbonyl process is now annually producing as a refined product thousands of tons of the purest nickel marketed.

It might be difficult to find a better illustration of the great importance of research to any nation whose people have the ambition to rise above the economic status of being "hewers of wood and drawers of water" among the nations of the earth. It is scarcely necessary to add that those responsible for the conduct of a business born of scientific research, developed by scientific research, nurtured by scientific research, and making every step in its progress by scientific research, nat-

urally regard scientific research as the key stone of success in production or in material progress in any direction.

### The Scope of Scientific Research

But I should like to add a few words in criticism of a tendency to narrow the use of the term scientific research to laboratory dimensions. If search in a laboratory by scientific means, let us say, for a method of recovering radium, or a few millionths of one per cent. of some other rare constituent (as is the case with several of the rare metals in our ores) — if this search may properly be spoken of as scientific research, why may we not apply the term with equal correctness to the search in the field by equally systematic and accurate means for the orebody containing millions of tons of ore, from which these and other metals are to be recovered? Search for geologically promising areas; in the Sudbury Nickel Area, further systematic search of such areas by extensive magnetometric surveys; careful recording of the observations, and plotting and study of the magnetic contours; systematic search of magnetically promising ground with the diamond drill, accompanied by accurate examination, sampling and analysis of the drill cores; careful recording, correlation and interpretation of the data thus brought to light, leading to the discovery of an important orebody: why can not a discovery of this kind by such means be placed to the credit of scientific research?

The crucial elements of scientific research, to my way of thinking, are: accurate observation; when necessary, assistance to observation by carefully planned testing or experimenting under known conditions; accurate recording of observed phenomena or facts observed, with correlation of the phenomena or facts observed, with other known facts or laws; if possible, clear interpretation of the observations; and, whenever possible, further testing of the interpretation. The search for new phenomena, new facts, or a new natural law may be among the stars, in the crust of the earth, within a chemical or physical atom, in human society, on a farm or in a garden, in an animate body or one of its organs, in the human brain or the mind itself — it matters not what the field — nor does it even matter what the ultimate motive — provided that the search will stand these tests, it becomes scientific research. This is the most powerful method yet discovered for solving our problems and making intellectual and material progress. It is equally applicable to the discovery of the phenomena and laws of nature, made with no ulterior motive beyond the advancement of knowledge; and to the discovery of the application of these laws in industry, with possibly a somewhat sordid immediate motive, but with the ultimate end in each case that human knowledge is broadened and humanity itself benefitted. It is the intelligence and intellectual honesty, rather than the motive, of the investigator, that determines whether or not a given investigation is properly to be classed as scientific research. Probably few scientific specialists engaged in research ever stop to analyze their own motives or to consider how complex these really are. If a research adds to the sum of accurate organized or organizable knowledge, it may, thus far, I think, properly be classed as scientific, even though it may be industrial in its aim. More and more as the domain of science widens is it found that accurate knowledge of almost every description finds a place in the scheme. As the human mind continues to widen its grasp of its surroundings, no doubt it will come to be admitted that every accurately ob-

served phenomenon or ascertained fact will find its place in the scheme of organized knowledge, which is science.

### Cultivate the Impulse for Research

This method of inquiry should be widely inculcated. It should become a national habit of mind. Indeed, the chief intellectual aim of educational institutions should be to fix in the minds of as large a percentage as possible of those passing through them this habit of inquiry, with insight into the means of satisfying it. The farmer who plants two similar measured plots of ground, one having a single altered condition, the other serving as a control; who keeps an accurate record of the result; and who draws a reliable inference from the experiment; is pursuing scientific research as surely though not as importantly, as is the physicist who, through the liquefaction of helium, achieves the closest approach to absolute zero yet made; or as is the graduate in medicine, working in a pathological laboratory, who discovers new means of diagnosing, preventing or alleviating disease. But the farmer will be greatly assisted, if, in addition to an intelligent insight into how to conduct such an inquiry, he has at least such knowledge of elementary science as will assist him to acquaint himself with what has already been accomplished, as well as to eliminate useless experiments. What is really needed in this direction is a change in our national mental attitude. In education having this end in view, it is not so much the quantity of knowledge imparted that counts, as the widespread stimulation of scientific curiosity and love of accurate knowledge, with insight into how to proceed to satisfy this desire.

The general kindling of the spirit of scientific inquiry or research is only one aspect of the national problem. The other centers round the importance of extending, in every way within national means, those researches carried on, either within or outside of our university and government laboratories, in larger private laboratories, on experimental farms, in connection with our soil, our forests, our minerals, or our fisheries, or elsewhere. These researches aim to widen the boundaries of knowledge by a study of natural phenomena, or of the laws expressing their relations, or of the best and most efficient means of controlling nature in the interest of man.

This work is generally highly specialized and sometimes costly, though the cost is usually very small relatively to the value of the results achieved. Its national success is conditioned on two factors: adequate financial support; and efficient means of selecting and training those gifted with special ability for conducting such investigations. The latter is clearly conditioned on a national scheme of scientific education as already discussed, if it is to reach the highest success. The aim of the present Conference is doubtless to emphasize the national importance of scientific research. Of even more fundamental importance is it that there should gradually be created, through education in the broadest sense, a wider interest in scientific inquiry, as the most solid and sure foundation of national material prosperity and well-being that can be laid.

A prospecting expedition into that part of New Guinea formerly in German hands, and now under mandate to Australia, has disclosed what promises to be an important placer gold and platinum field. Concessions have been granted on the Waria river in Morobe district.

### THE INSTITUTE'S PRESIDENT

Mr. W. R. Wilson, President of the Canadian Institute of Mining and Metallurgy, is one of the foremost of Canadian mining engineers. Born and bred in a colliery district in England, his experience in coal mining actually began in childhood. On the foundation of a generous technical education and an initial practical training under a father who was himself an eminent mining engineer, he has built a reputation that has spread through three continents. After an initial experience in Nova Scotia Mr. Wilson advanced to positions of responsibility in English col-

Mr. W. R. Wilson

lieries. Then his services were requisitioned for use in Pennsylvania. From Pennsylvania he came to Fernie, British Columbia, where he laid the foundations broad and deep for the colliery development that he now directs. South Africa next claimed his services for three years, when Canada regained him. Twelve years ago Mr. Wilson took hold once more of the Crow's Nest Pass Coal Company, and now has developed the collieries round Fernie into one of the principal producing districts in Canada. The Institute has been fortunate in having Mr. Wilson as its President during the past year.

During 1922 Australia produced 758,303 ounces of gold as against 757,431 ounces in 1921. Two-thirds of this came from West Australia. Ten years ago the production was over two million ounces. Lack of new mines and the high cost of labour and material are held accountable for this decline.

## Hollinger Consolidated Makes New Record

The twelfth annual report of Hollinger Consolidated Gold Mines makes further standards of excellence. In 1922 the gross production from 1,491,381 tons milled was valued at \$12,726,549.77. As that brought the Hollinger grand total since the beginning of milling operations, to \$62,747,529.32 (of which \$60,566,025 was recovered) it calls for no elaboration or encomiums to convince the student of mining statistics that the presentation bears the stamp of authenticity plus an assurance of more than ordinary longevity.

Not only did Hollinger in 1922 produce nearly as much gold as the whole of Canada did a year or two ago, but the further \$43,269,827 contained in the proved and indicated ore reserves makes the grand total gross value of what has been extracted and what is practically in sight, \$106,017,356. Year after year these mines have gone from peak to peak, despite recurring

Nor was that all. The premium on United States Exchange brought \$167,901.65, and interest on investments and other income, \$382,591.83, so the total of income was \$12,824,608.25. The net profits from operations amounted to \$6,478,604.12. Taxes took \$518,223.67; depreciations and donations, \$813,690.18. This brought the net profit to \$5,146,690.27. From that \$3,198,000 was paid out in dividends, leaving \$1,948,690.27 to be added to surplus. The surplus then amounted to \$5,909,469.77, but the balance sheet shows net current assets of \$6,331,220.56, as follows:

operating difficulties, yet the ore reserves are higher than ever.

## The Year's Operating Results

At the end of 1921, the total of the reserves was 4,392,917 tons, estimated at \$42,716,027. On December 31st last the reserves were placed at 4,608,223 tons valued at \$43,269,827, the average of the mines being \$9.39 per ton, this notwithstanding the 1922 results, as follows:

Against this there were current liabilities of \$1,604,759.18, on account of wages and bills payable, \$888,750 for balance of purchase of Schumacher Gold Mines, and \$300,000 for Dominion Taxes for 1922. It is characteristically conservative to have an item of \$787,999.95 for depreciation on a plant that has cost \$5,253,333.01, on which \$3,615,954.42 has been written off, and the present valuation of which now stands at \$1,637,378.59, although \$1,070,076.25 was expended

upon it in 1922. Interest on investments' and other income amounting to \$382,591.83 may be said to be contributing 11.9 per cent. of the current annual dividend.

#### On a Manufacturing Basis

Liquid assets of \$7,935,979.74, the maintenance of a surplus that is more than ample for all contingencies, together with the gross value of the proved and approximated ore reserves, lend emphasis to these statements of President Noah A. Timmins:

"As stated last year, until there is a satisfactory solution of the power situation, upon which the whole programme of the contemplated extensions at the Mine depends, the Directors feel that any increase in the dividend must necessarily remain in abeyance, but shareholders may be assured that the matter will receive the earliest consideration of the Directors when the power situation has been cleared and the very large financial obligations provided for.

"At the risk of repetition we must again remind shareholders that the dividends they receive from a Mining Company should be treated, to at least fifty per cent thereof, as a return of Capital, because every dividend paid represents so much ore taken from the Mine which there is no means of replacing. It is again gratifying to report a substantial increase in the number of our shareholders who now number approximately 5,000 as against 3,500 at this time last year.

"The increased taxation imposed upon the Company's operations is a matter of grave concern to your Directors. The Hollinger Company has grown out of the speculative stage and is now established as a manufacturing industry and it would be well for the shareholders to realize that in addition to the large item in the Profit and Loss statement paid as direct taxation for the current year, the industry is further burdened by indirect taxation, amounting in all to considerably more than the direct taxation. The greater part of our mining supplies is subject to a tariff duty of 27½% which must be paid either through the Customs or to the sellers of similar articles in Canada by way of an addition to the price of the article purchased, on top of all of which there is a large sales tax, and this, in the case of an industry which should, in the interests of the public, be absolutely free from any direct or indirect taxation."

#### The Sole Deterrent

The power difficulty is the solitary deterrent. Were it not for this the company would have been free to proceed with a demonstration that will be of national importance and international interest. General Manager Brigham explained the position and policy to be followed, when he inserted this in his general comment:

"Further annoying power shortages have occurred during the year, which very materially affected the tonnage and costs.

"The regular annual occurrence of this embarrassing situation demonstrates that this Company will have to look to some other source of supply in order to complete the plans of the Hollinger, to bring the mine and plant to its highest economic development and efficiency.

"As is well known, the veins in the Porcupine district do not have sharply defined walls and

the ore often extends into the country rock with gradually decreasing values.

"To mill the lowest payable grade of ore it will be necessary to work the whole plant on a larger scale, for the reason that if this low grade portion of ore from the walls of the stopes is ever to be mined, it must be taken while the operations are in progress."

#### Rate of Money-Making

It becomes important in the national economies to note that the average daily crushing was 4,097 tons, regardless of power interruptions. As the total crushed in the year was 1,491,381 tons, some idea may be framed as to the rate of Hollinger money-making. Taking 350 days as a basis for calculation, at the stated daily crushing that would total 1,433,400 tons. Dividing by 350 the gross recovery of \$12,274,114.77, makes it clear that the daily contribution of wealth was \$35,069, or thereabout — \$1.461 an hour. While doing that the ore reserves were increased from 4,392,917 tons estimated at \$42,716,027, to 4,608,223 tons estimated at \$43,269,827, the average of the mine being \$9.39 per ton, compared with \$9.72 at the end of 1921. Of the tonnage milled in 1922, 465,928 tons came from above the 425-ft. level, and only 33,926 tons from below the 800-ft. levels, where, Mr. Brigham states, "the development has been highly favorable, particularly on levels 950, 1100, and 1250". Discovery of 97 vein on the 425-ft. level, and its development for several hundred feet, with an average value of \$30.82, was a remunerative incident in mines that have been producing for twelve years and still have 1,216,027 tons valued at \$12,990,707 above the 425-ft. level; 1,496,939 tons valued at \$16,074,718 between the 425 and 800-ft. levels, and which take credit for 677,779 tons worth \$6,672,448, below the 800-ft. Moreover, surface outcrops estimated at 209,681 tons worth \$2,183,360, have to be added to the \$12,990,707 known to exist above the 425-ft., without dwelling upon a portion of the 1,007,797 tons worth \$5,348,594 in veins of \$6 grade. This latter ore is not going to be a negligible factor, once the mill is enlarged and power is available. The management is proceeding to place the mines in a position where it will treat the lowest grade consistent with due economies. The greater the tonnage milled, the lower the cost should be, automatically. In 1922 the operating cost per ton milled, was \$4.2551. In 1921, the cost was \$4.8698. Taking this betterment as an index to what should follow when 7,000 tons or so is going through, it is deserving of notice that the 1922 yield and grade were equally noteworthy. In the 1922 gross value and average grade as given, the exchange premium on bullion is not included, as it was in 1921. Mr. Brigham explains that, in reality the added exchange in 1921 increased the actual yield of \$8.74 by 93c., hence the average grade appeared as \$9.67, whereas the \$167,901.65 realized from the premium in 1922, represented only 11¼c. The difference between the 1921 and 1922 recoveries was 21c, due to the exchange premium being only nominal of late. The difference in operating costs in favor of 1922 is a compensating factor.

#### Awaiting the Chance and Preparing for it

President Timmins took the opportunity, on behalf of the Board, to detail the efforts to obtain power, wherever it was to be had. They applied for the Long Sault Rapids on the Abitibi River. It was refused to the company because verbal application had been made for that power by the Abitibi Power & Paper Com-

pany. The Hollinger Company then applied for the water power at Island Portage, approximately 76½ miles away. A draft lease of this is about to be signed. Then there will be a forward movement. To this end, expenditures upon plant in 1922, were:

|                          | Buildings    | Equipment    | Total          |

#### Cost of the Schumacher

The Schumacher purchase is carried at cost: \$1,343,541, the balance due being \$888,750. While surface equipment has been provided for the Schumacher, there are no estimates as to its mining position, further than that President Timmins states the veins of the Acme property of Hollinger have a distinct tendency to dip to the east and pass into the Schumacher territory at depths between 2,000 and 2,500 feet. It will be some time before that depth is reached if the Acme section keeps on growing.

#### LONDON ENTHUSES OVER PORTLAND CANAL

It is a mistake to suppose the World Metropolis is phlegmatic or moving slowly, like all great bodies. London is no different from its contemporaries when it runs across something that will induce "pep." The ordinary event is the merest pebble dropped into an ocean of people, who may seem unruffled, but who, in their own way, are far removed from fridity.

It is the hardest and easiest place to convince; yet when London is going, the going is good, and the latest proof of this is the avidity with which Throgmorton street and its environs entered into the market for Selukwe company shares, following upon the report that the extension of the Premier Gold Company's ore zone had been intersected by the British Canadian Silver Corporation, operating in the Portland Canal district of British Columbia, holding properties and interests in properties surrounding the Premier and adjacent to Indian Mines, the latter controlled by Montreal and Toronto.

No sooner did the cables announce the cutting of what was believed to be the Premier section, than Selukwe shares took three octaves at a jump—soared from a five shillings register to twenty-seven and sixpence. The incident prompted London to consult the maps and start the machinery. The oversea speculator is gregarious. Portland Canal at last appealed to him, and here are the reasons for it, as set forth by the Financial and Mining Editor of "The African World", which specializes in all things African:

#### The Selukwe's Promising Venture

In 1919 the Selukwe Company acquired certain options over a proportion of the share capitals of

three Canadian mining companies, which options it transferred to a subsidiary company, known as the British Canadian Silver Corporation, Ltd. This company has a capital of £400,000, in 5s. shares, the whole of the issued capital being held by the Selukwe Company. The options concerned the B. C. Silver Mines, Ltd., the Bush Mines, Ltd., and the Salmon Bear River Mining Company, Ltd., all incorporated in Canada, and owning properties in the Salmon River district of British Columbia. The subsidiary of the Selukwe now holds 40 per cent. of the capital of the B. C. Silver Mines, a small interest in the Bush Mines, as well as an interest in the National Mines. It also holds as its own property the claims known as the Cascade, which may prove to be of considerable future importance in the working of the B. C. Silver Mines. In between the claims of the B. C. Silver Mines is sandwiched the property of the Premier Gold Mining Company, an American concern with a capital of \$5,000,000 in \$1 shares, which are at present valued on the New York Stock Exchange in the neighbourhood of \$50 per share. Of its capital the Premier only received about \$260,000 in cash for working capital. It distributed last year to its shareholders dividends totalling \$2,700,000, which, with a dividend paid the previous year, brings up the total distribution to \$3,150,000. The Premier Mine appears to possess three lodes, of which, however, one lode is contributing the bulk of the ore possessing high values in gold and silver. This lode should be found to run through the northern claims of the B. C. Silver Mines, and may have been cut, for a cable published on January 18 reads as follows:—"Have crosscut lode 25 ft.; we have so far not met with the footwall. The quartz is well charged with pyrites galena. Assays vary up to \$25. Premier Gold Mining Company have ore bodies of the type. Fully expect developments on the lode to get rich ore same as Premier Gold Mining Company, Ltd. Work proceeding steadily; will duly advise you by cable as regards important developments."

#### District and History

Salmon River district lies in Northern British Columbia, about eleven miles north of Stewart, which is situated at the head of the Portland Canal, one of the largest fiords which penetrate the coast range. On the west the district adjoins the boundary between Alaska and British Columbia. The eastern boundary is formed by Bear River ridge, which trends almost north and south. The map area is triangular, and about sixty square miles in area. The district contains the headwaters of the Salmon River, which flows southward into Portland Canal at Hyder, Alaska. It is accessible by a wagon road and trail from Stewart up Salmon River, Stewart being reached by steamship service from Prince Rupert and Vancouver. The district first came into prominence about 1910 on some very promising discoveries, which, however, did not materialise, and interest in the camp remained dormant until a couple of years ago, when a Canadian named R. K. Neill made a careful examination of the district and the old workings, and came to the conclusion that exploratory operations had been

conducted parallel to instead of across the formation. His judgment was confirmed when he cross-cut a few feet in one of the tunnels, and came across a big ore body showing high values. The property — now the Premier — was promptly secured by big New York interests, including the Guggenheims. The general trend of the formation is north-east, and there is a strong body of ore outcropping along the ridge on which the B. C. Silver claims are located, which appears to indicate the continuity of the formation, although owing to climatic and other conditions most of the value in the outcrop has been washed out, high values only commencing at about 200 ft. from the surface. The mines are worked by adits, so that there is no expense in hoisting or pumping. The B. C. Silver Company is cutting a tunnel across the run of the Premier lode, where it should come into its property, the horizon being equivalent to the second level of the Premier Mine, with the results already mentioned. The Cascade claims, belonging to the subsidiary of the Selukwe, will, outside any direct mineral value, allow of tunnels being driven into the hill-side practically down to the water level, and prevent the crowding out which might conceivably have resulted by the buying up by others of the surrounding properties. It is too early yet to express any definite opinion as to the continuity of the rich values into the B. C. Silver claims of the extraordinary high values of the Premier although the outlook for doing so is distinctly promising. On the southern block of claims belonging to the B. C. Silver a parallel lode has been located, while it is probable that a third lode located on the Premier, to the west of the main lode, will also be found in the northern block of B. C. Silver claims, a formation having been struck by a borehole. There appears to be every indication that the Selukwe has secured an extremely promising asset in its British Columbia interests, and further particulars respecting developments will be awaited with interest.

#### Overstatements Not Justified

This is the London story. It confirms the Selukwe find. Evidently the Premier, Selukwe and Indian Mines have neighboring extensive areas, owned outright or on joint account with others. The values quoted in the cable resemble those of the Indian more than those of the Premier, but if the width is maintained London enthusiasm should result in more capital going to that locality.

It is rather overdrawing it, however, to claim that "the Premier only received \$260,000 in cash." Working capital exceeded that, for an aerial tramway had to be constructed, roads made, a mill built and development prosecuted. While it is a fact that the Premier company made a "total distribution of \$3,150,000," it is stretching it to state that the \$1 Premier shares "are at present valued on the New York Stock Exchange in the neighborhood of \$50 per share." That would make the market valuation of the Premier capital issue, \$250,000,000. Really the shares occasionally are being dealt in at about \$4 (between \$3 and \$4) on the Curb, not the Stock Exchange.

Conceding the auspicious outlook confronting the Selukwe, because of its interests in and about the Premier, and according to Portland Canal a large measure

of commendation, the facts carry with them an admonition that London should take "well enough" at its worth. The author of "The African World" comment is scrupulously circumspect as a rule. His informants might be given to understand that exaggeration arouses incredulity and invites discredit, which all interested in Portland Canal desire to avoid, since the prospects are sufficiently flattering without any fanciful additions.

### LETTERS FROM READERS

#### Geological Maps Wanted

To the Editor,

Canadian Mining Journal.

Sir:

The territory through which the Canadian National Railway runs, between Sudbury and Port Arthur, needs prospectors and needs them bad. Suggestions have been made from time to time in order to attract prospectors into this promising territory, but without success. It is getting to be a well recognized fact that the Ontario Dept. of Mines through their geological reports, maps and prospectors' classes have developed a group of prospectors who are giving a good account of themselves. Years ago the Old Timer rambled, hit and miss fashion; but we must give him credit for his initiative. Geologists, geological reports and maps meant little or nothing to him. He claimed he could see just as far into the ground as any other rock hound. But after Dr. Miller had declared himself quickly and correctly at Cobalt, and his assistants had done their efficient work up in the gold camps, the prospector began to sit up and take notice. Now, instead of rambling off on his own, he must have his geological map and reports, with which he has been well supplied along the T. & N. O. country, and that's one of the reasons why he can't be pried loose from that district. Yet you can't blame him; the proper order of prospecting exists along that line. The geologist goes *ahead* and maps the porphyry intrusions and the prospectors follow on his heels. Now, by starting in on these two promising belts of rock that cross at Mileage 81 and Ground Hog respectively on the Canadian National main line and working from the railroad in, and mapping in detail to show porphyry intrusions, then the modern prospector in these parts will be given some inducement and encouragement in his efforts that will benefit us all.

Gogoma, Ont.

Tom Saville.

#### OIL SHALE EXPERIMENT ABANDONED

The attempt to extract oil from shale in New South Wales by means of firing it in the ground and collecting the oil thus distilled, has been abandoned, according to an announcement by Mr. John Fell, who was conducting the enterprise. The high cost of Australian labour and the low price of imported oil are given by Mr. Fell as the principal reasons why these remarkably rich oil shales cannot be worked at a profit.

During the year 1922 Britain regained the whole of her former export markets for coal, lost during the war time. The importance of this can be gauged from the fact that it is principally by means of the export of coal that Britain pays for the food that must be imported. The natural product next in importance to coal as an export, but a poor second, is China clay, obtained from the famous pits in Cornwall, which is shipped to all quarters of the globe.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**POWER SHORTAGE.**—Porcupine mines have had notice of a seasonal power cut within a week, and they are now receiving only about one-half their normal power requirements. The shortfall came rather as a surprise, because for some time past it has been announced that the Sandy Falls plant would be delivering an additional 3000 h.p. in February. The water in the Mattagami river, however, appears to be exceptionally low, and it is believed that the power company is now down to the normal flow of the river. The Northern Canada Power Company announces that it will proceed this year with the development of Kenogamissi power, where it is anticipated that from 3000 to 5000 additional h.p. is available. This involves the diversion of the Grassy River into Kenogamissi Lake, and the estimated expenditure is approximately \$1,250,000. Construction work on the Sandy Falls plant is being rushed, and it is now hoped to have the first unit in commission in March with the second unit a month or so later. During the past few years there have been recurring power shortages, which the power company now hopes to overcome with the proposed development.

**HOLLINGER ANNUAL REPORT.**—The annual report of the Hollinger Mine for the year ending December 31st, 1922, shows that the company established new records of production and profits. During the year they treated a total of 1,491,381 tons, averaging \$8.53 a ton, as compared with \$8.74 for the preceding year. The total income for the year was \$12,824.08, an increase of \$2,500,000. Operating charges increased \$1,100,000, to \$6,346,000, and the net profit was \$5,146,690, an increase of \$1,100,000. Total dividends paid during the year amounted to \$3,198,000, the same as in 1921, leaving \$1,949,000 to be carried to surplus, which now stands at \$5,910,000. The assets are shown at \$32,000,000, and include \$1,343,000 for the Schumacher Mine, which was purchased during the year. Current assets in excess of liabilities amount to \$5,572,000, and ore reserves are estimated at 4,608,223 tons, averaging \$9.39 a ton, a total of \$43,270,000, which is practically the same as for the preceding year. The report makes special mention of the power shortage and states that had it not been for these that the total production and net profit would have been materially greater. The report also makes the definite statement that on account of the power troubles, in order to attain the production and efficiency desired, it will be necessary for the company to develop its own power, and that the question of increased dividends will remain in abeyance until this matter is settled. Developments under ground during the year were favorable, particularly on the 950-foot, 1100-foot and 1250-foot levels, where all veins so far exposed are of good values and widths, as compared with occurrences on the upper levels.

**PORCUPINE.**—Work on the West Dome Lake Consolidated has been stopped for the time being. The company made an attempt to unwater the mine with steam power, but this has not proved satisfactory and the directors have decided to await the spring freshets, when it is hoped that electric power will be available.

**KIRKLAND.**—It is stated that the Tonopah Mining Company of Nevada is investigating the Woods property in the Kirkland district, with a view to its acquisition.

The taking over of the Kirkland Lake Proprietary's interests in the Sylvanite property involved a larger sum than was originally mentioned. The total amount involved is now officially stated to be \$1,130,000, of which \$400,000 is to go into the Sylvanite treasury for the development of the property. The Kirkland Lake Proprietary owned 891,000 out of 3,000,000 shares of Sylvanite and will receive \$730,000 for these. This is believed to be the largest amount of cash ever paid for a gold mine in Northern Ontario. The purchasers are connected with the Wright Hargreaves property adjoining. The main shaft will be sunk to a greater depth and a considerable amount of development work will be done. With this large sum going to the Kirkland Lake Proprietary, that company will be in a position to pay off all its obligations and to develop thoroughly the Tough-Oakes and enable a greater tonnage of ore to be placed in sight.

Arrangements have been made to install a small mining plant on the Highland-Kirkland. It is understood that the plant will be installed immediately in order to take advantage of the winter roads. The property is being developed by Toronto and New Liskeard people.

**DANE.**—The excitement in connection with the new gold district of Rouyn Township in Northern Quebec is assuming the aspects of an old time rush. The country is rapidly being staked far outside the limits of the original discoveries, and with the recent completion of the winter road from Dane on the T. & N. O. Railway, it is now possible to bring in mining equipment and supplies. Several diamond drills will be operated, and it is anticipated that a great deal of work will be done during the coming spring and summer. Most of the staking is snow staking, and there has been as yet no opportunity to size up the possibilities of the country, outside the original discoveries. These, however, are very good, particularly on the Powell property, where the vein has been traced for over a mile in length and shows good values over substantial widths. The geological conditions are somewhat similar to Kirkland Lake, and old time prospectors state that the discoveries are the most important since Kirkland.

The milling plant at the Argonaut Mine is practically completed, and should soon be in operation. The process being used is somewhat different from that used in the mills of Northern Ontario in that flotation will first be used to eliminate the copper contents. The tailings from the flotation plant will be cyanided. Results on the 500-foot level are understood to be very satisfactory, the ore being of a very good grade.

The directors of the Keeley Mine announce the declaration of an 8 per cent. dividend, which calls for a disbursement of \$160,000. The headquarters of the company have recently been transferred to Canada and the assets turned over to a new company with a capital of \$2,000,000. Mr. J. Mackintosh Bell is consulting engineer and Mr. Hamilton B. Wills is president.

## NOVA SCOTIA

**LAWLESSNESS IN SYDNEY.**—Nova Scotia is just beginning to realize that in times of acute industrial strife, such as we have lately had at the Sydney steel works, the law is openly defied and flouted and mob rule in all its riotous vagaries governs. Neither life nor property is protected on such occasions, the rights of free citizenship are denied, courage to do what is right is deemed foolhardy, and the few men who dare to exercise that courage are held up to open scorn and ridicule. Mob intimidation, running all the way from blocking the principle roadways leading to work by hordes of howling, jostling pickets, forcibly holding up workmen, and vehicles of all kinds, to placing railway ties across the tracks, stopping trains, and searching these for "scab" labor, detaching locomotives from cars containing supplies for the steel plant, to openly parading with guns, is only part of the picture of the late steel strike. Then when the strike was declared off hundreds of men paraded to the premises of merchants who supplied the maintenance men trying to save the steel property for the use of these very strikers, entered the stores, called vile names, stormed and abused, and threatened the boycott to the ultimate strangling of business and the starvation of all connected with it. This disgraceful and lawless conduct, coming after the majority of the workmen had voted to go back to work pending an investigation in the result of which they had agreed to concur before it was made, shows how little the rank and file realize the humiliating position in which they have been placed before the public. The newspapers, public opinion and the majority of the workmen were all against the strike but were helpless in the hands of the minority, who were quick to gain control of the situation and hold it until they were willing to let it go. The investigation found the offending employee at fault and he was kept off the works, yet there is every evidence that more strife is being fomented and a repetition of the same revolutionary scenes may again be enacted.

The rabid "reds" claim that the strike was a howling success. They point out to their followers the gains made, which actually amounted to nothing, for their case was lost from the very beginning. But they succeeded in setting at naught all law, making a mockery of all constituted authority, and in riding rough-shod over everything that came in the way. Inflated with the feeling of false victory, there seems to be a determination to try their strength again, and if drastic and prompt action is not taken and law enforced, it is difficult to understand, how progress can be made or business stabilized and industry kept going. The workers are in the hands of the "reds", and while the majority of the workmen are not revolutionary at heart they are permitting themselves to be used for the destruction of the very industry by which they hope to live.

When the country awakes to the real danger hanging over the two large industries of Nova Scotia, they will make haste to save them. Unfortunately peaceful citizens have short memories and soon forget the unpleasant experiences of the past. The Cape Breton coal strike is not so far away as to be forgotten, and the same dominating, ruthless spirit of that crisis was again seen in Sydney last week, and may yet be aroused to more intensified bitterness and violence by the loud mouthings of irresponsible leaders.

If the right to go to work had been guaranteed to the steel workers, most of whom are honest and fair minded

men, we would not now be facing a doubtful and critical situation, for these men would have settled the question at issue and peace might have been with us for years to come. They were in the great majority then, and would not have been deterred by a minority mob element from the faithful performance of their duty. A recent statement of one of the leaders goes to show that trouble was created for the purpose of organizing the workmen as unionists. With organized labor, well led, we have no quarrel; but if men are duped into joining such an organization, who can say that the same tactics of falsehood will not be employed in running the union by the very men who planned the first deception?

**GOOD WORK ON NATIONAL RAILWAY LINES.**—The Canadian Government Railways do not often come in for much praise; indeed the custom has been to "knock" them; but those who know what has been accomplished in Nova Scotia this winter cannot withhold good words, much less criticism. The winter has been very severe, with long periods of hard frost. The lumbermen of Cumberland had to leave the woods early in January because of heavy snow. About the same time there were upwards of 30,000 tons of coal in cars between the railway yards of Truro and Springhill Junction, yet within the short period of a little over two weeks this coal with much other freight was carried to its destination and relief given to the districts short of coal. All this time the collieries of Pictou and Cumberland were kept running steadily.

**SELECTION OF RESCUE APPARATUS.**—A test of four different types of self-contained rescue apparatus is being made by the Dominion Coal Company to determine which they will select. The experiment is being conducted along scientific and practical lines. The men and machines are working in the same kind of atmosphere that would be found in a coal mine after there had been an explosion, and the work done is the same as that to be performed by rescue parties in times of mine disaster. In all twelve days will be consumed in making the test, four above and eight below ground. Both men and machines are put through an examination before and after the two hours test is made, and an analysis made by a chemist of the carbon dioxide left in the breathing bag. A full report will be published in the *Canadian Mining Journal* after the test is completed.

## BRITISH COLUMBIA

**PORTLAND CANAL.**—The definite proving of the extension of the ore body below the fourth level on the Premier Mine and the opening up of high grade ore of the same character on the adjacent property of the B. C. Silver Mines Ltd. are two recent important developments in the Portland Canal camp, north of the town of Stewart.

G. D. B. Turner, vice-president and general manager of the Indian Mines Ltd., states that the whole atmosphere in this section has changed in a month. Confidence in the permanence of the camp has taken the place of doubt and large prices are being asked for prospects which may become valuable but have not been proved. Eight properties have been working throughout the winter, Mr. Turner reports, and two or three will be shipping ore before the snow goes. The Indian has been under development without interruption, a considerable body of milling ore has been located,

and the management feel that they have every chance of finding the richer ores.

Only a few weeks ago Mr. Turner inspected the Premier, B. C. Silver and Mobile as well as the Indian Mines. As he is a conservative as well as a thoroughly experienced engineer, it is worth while quoting his impressions:

"For a time it was very questionable how far the ore bodies of the Premier would be below a certain horizon and so it was feared that some values might give out below No. 4 tunnel. Not only are the ore bodies continuing in the fissures but some new ore bodies have been discovered. This, coupled with the new strike made on the B. C. Silver, has added great confidence. The Indian Mine, lying further to the northwest, was perhaps the most actively worked mine during 1922, apart from the Premier. The Indian has employed 17 men since last April. While high-grade ore in quantity has not yet been found, large bodies of good commercial ore already have been disclosed, the ore of which is not quite blocked out. There has been sufficient in sight to satisfy me that a milling plant will be required for the property by next autumn. McCuaig Brothers, of Montreal, are showing a very active interest and are lending their support to the Indian Mine. In the early days these men were connected with such British Columbia properties as the Payne, War Eagle, Le Roi, and North Star."

C. A. Banks, managing director of the Canadian Silver Corporation, Ltd., controlling the B. C. Silver and other properties in the Salmon River section of Portland Canal, when interviewed in Vancouver stated that the crosscut tunnel on the B. C. Silver has been driven 1050 feet and that it has cut the eastern extension of the Premier Mine vein. He says that the enclosing rocks and the gangue of the vein itself are identical with that of the Premier. The vein, which has been crosscut twenty five feet, consists of low-grade ore as far as driven. The footwall has not been reached. The results of development have been decidedly encouraging and it is hoped that a shoot of the high-grade will be uncovered on the footwall or by drifting as in the Premier.

OMINECA AND CARIBOO.—Discussing the northeast sections of British Columbia before the B. C. Chamber of Mines, J. D. Galloway, resident mining engineer, said that J. T. Duthie's two properties on Hudson Bay Mountain, near the town of Smithers, were promising. One carries good gold values and a considerable zinc content while the other is a high-grade silver-lead property. The presence of freibergite and ruby silver makes this ore very rich in silver and the lowest tunnel on the vein is showing up phenomenal ore. Steady shipments of ore have been made. A gold prospect in the Babine Range east of Smithers is being opened up by a New York company and with a small expenditure a very large ore-body has been exposed on the surface. Engineers are now on the ground arranging for the equipment of the property with machinery for deep development.

As to the Cariboo, he predicted a great revival of activity. Many companies were engaged in testing by means of Keystone drilling and other methods the district's low grade placer gravels. Lack of water made the 1922 season a poor one for hydraulic work but notwithstanding the gold production was nearly three times what it was in 1921.

The Cedar Creek discovery east of the town of Quesnel Forks was important as a source of gold and as an in-

dicator of a new type of placer deposit, which would cause a re-prospecting of the whole of the Cariboo. The gold bearing gravels in this camp are portions or remnants of a very old high level Tertiary channel. They are characterized by extremely rich ground, running from \$25 to \$500 a cubic yard. Rich ground has been found on three leases and many leases in the vicinity of the discovery warrant thorough prospecting to find possible continuations of the gold bearing channel. A production of \$125,000 had been made by the camp last year, principally by means of rockers, a very primitive and small scale form of mining. With more improved mining methods a much larger production will be made in 1923.

NEW MILL FOR ANYOX.—H. S. Munroe, general manager of the Granby Consolidated Mining & Smelting Co., is definitely quoted as stating that the proposed new concentrating mill at Anyox, the Company's smelting centre, will be constructed, that it will cost approximately \$500,000, and that it will be ready for operation early in 1924. Work will start this spring and the mill will have a capacity of between 1200 and 1500 tons of ore a day. Several millions of tons of ore, which it is not economical to treat by smelting direct, are reported to be blocked out and ready for mining as soon as the additional plant is in shape to handle it. With the advent of the mill it is expected that one furnace of the smelter will be closed down.

Further descriptive details of the concentrator are as follows: Its site will be on the side-hill overlooking the water and below the present "high line" railway track. The ore will first be crushed by large crushers now in place at the mine and thence transported over the "high line" railway. A fine crushing plant will reduce it further and conveyors then will transport the material to storage bins at the head of the mill. Oil flotation will be used, the plant consisting of a crusher building, conveyor system, concentrator building, de-watering tanks and filter building. The plant will be designed for an ultimate capacity of 3,000 tons of ore a day, in three units of 1000 tons nominal capacity each. Construction work on the first unit will start as soon as plans can be drawn and material assembled. In order to handle the concentrate certain changes will be made in the smelter, which may include the erection of a new sintering plant. Machine shops, electric shop, and foundry will be altered or enlarged in order to provide more efficiently for the construction work in view.

The Outsider Mine, Portland Canal, which the Company controls, is expected to be shipping ore to Anyox towards the close of the year.

GRANBY PLANS.—The plans of the Granby company, when carried to fruition, will enormously increase the scope of its operations in British Columbia. Recent construction, together with that projected, in connection with the Anyox plant involve an expenditure of about \$1,200,000. This figure is obtained by adding the estimated cost of the new Mill, \$500,000, to that of the lately undertaken and now almost complete storage dam, which runs to nearly half a million, and that of an addition to the hydro-electric plant at No. 1 Power House, which approximates \$200,000. These works seem to assure the permanence of Anyox as a mining centre and would appear to indicate confidence, not only in the Hidden Creek Mine, but in the possibilities of such other properties as the Outsider, now being developed, and prospects in the Portland Canal region in which the Company is reported to be interested.

Attention, however, has lately been focused on the Granby Co. more on account of the acquisition of the mine and mill of the Canada Copper Co. at Copper Mountain than for any other reason. It is understood that the concentrate from this mill will be treated by the Consolidated Mining and Smelting Company at Trail as soon as the copper smelter there is re-opened.

**THE IRON ORE SURVEY.**—The survey of the iron ore deposits of British Columbia, which was started by Dr. G. A. Young, of the Canadian Geological Survey last year, will be resumed as soon as the season opens. Dr. Young, who is in Ottawa, is making preparations already to take up the work where it was left off last year. At the last session of the British Columbia legislature the expenditure of the sum of \$50,000 was authorized to permit the obtaining of information that Dr. Young must have to make an authoritative report on the tonnage of suitable iron ore available for the maintenance of an iron industry. Detailed plans have not yet been formulated but it is expected that some properties will be diamond drilled and other exploratory work done this summer upon Dr. Young's recommendation and under his supervision. Hon. Wm. Sloan, the Minister of Mines for the Province, states that every possible assistance will be given the investigator in order that the facts as to provincial iron ore resources may be authentically established.

Meanwhile it is reported that a syndicate of Spokane business men is taking an interest in the iron ores of the interior of British Columbia with a view to their development. Fred Starkey, commissioner for the Associated Boards of Trade of Eastern B. C., is compiling all information available regarding these deposits for the use of this syndicate.

**TRAIL ORE RECEIPTS.**—Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co. of Canada, for the first week in February totalled 9264 tons, bringing the aggregate for the year to 45,242 tons. The fact that the custom ore receipts for the year already amount to 5246 tons indicates that there is much greater activity generally in the mining industry of British Columbia's Kootenay and Boundary camps. The shipments to the smelter from the 1st to the 7th of February follow:—

|                                 |         |
|---------------------------------|---------|
| Black Rock, Northport . . . . . | 42 tons |
| Bosun, Silverton . . . . .      | 32 "    |

| Surprise, Republic . . . . .    | 145 "   |

Total . . . . . 9264 "

**CLINTON.**—The Whitewater area, Clinton district, is being much discussed at present. Here E. J. Taylor, a prospector, made a find two years ago which he has bonded to G. A. Crane and associates for \$300,000. Since then there has been much prospecting and some 500 claims have been recorded. This sounds as though the ground had been well covered but, if returned miners are to be taken literally, the possibilities of the district are far from exhausted. Mr. Crane, an English engineer, who has been into the Whitewater valley, seems impressed and is giving his personal attention to the opening up of the Taylor property. C. A. Baldwin and the Gibson brothers, experienced miners, have acquired a number of claims. They located the Motherode and Amazon groups on Motherlode and Orofino mountains, samples of whose ores are said to have given

returns of \$2400 to the ton. They are reported to have bonded these properties for \$550,000. The Spokane group on MacClure Creek is said to have been bonded for \$200,000. R. W. Wood and A. B. Triles, whose names are well-known as among those early associated with the Premier Mine, are interested in some Whitewater prospects. Major A. W. Davis, resilient mining engineer, recently said that this district gave excellent promise, that several of the groups of claims bonded would be opened up this year, and that there was an immense virgin territory lying to the west of the Whitewater between Chilco Lake, Bute, Toba, and Jervis Inlets.

**PIONEER DEAD.**—One of the pioneer mine operators of British Columbia died recently in the person of Captain F. P. Armstrong, who about thirty years ago operated the Ruth Mine at the head of Vermont Creek in the Golden mining division. Later he worked the Giant Mine, a low-grade lead property, in conjunction with Thomas Jones, the discoverer of the Paradise Mine. Ore from both properties was shipped up the Columbia river to Golden and thence transported by rail to the smelter.

Representations are being made by the Associated Boards of Trade of British Columbia to the Dominion Government in favor of the immediate establishment in the Kootenays of an Ore Testing Plant.

The Granite-Poorman Mine at Granite is reported to have been bonded by Alfred F. Jerome and Associates whose intention it is to start work there immediately.

D. J. Williams, formerly manager for the Rocher de Poile Copper Company, has been appointed manager of the Drum Lummon Mine, Douglas Channel.

Ronald McKinnon, a recent arrival at Edmonton Alberta from Fort Norman, states that the oil tanks at the Fort Norman well are full and that no drilling has been done since the freeze-up. A crew is on the ground ready to resume operations as soon as weather permits.

**THE CUMBERLAND EXPLOSION.**—Officials of the Canadian Collieries (D) Ltd. and employees of the company held a meeting on Thursday, the 15th February, when the latter demanded that before No. 4 Mine, Cumberland, where 33 men recently lost their lives as a result of an explosion, was re-opened the long-wall system of mining be abandoned in favor of the pillar and stall method and that all underground Oriental workers be expelled.

The management's reply was that Chinamen could not be done away with until the changes incident to the abolition of the long-wall workings were complete. To that change there was no objection. When this had been accomplished Orientals would no longer be employed in the mine.

A standing vote indicated that on this understanding the men were willing to return to work and doubtless in the course of a few days that part of No. 4 Mine which was not affected by the disaster again will be on a producing basis.

On Friday the 16th an Inquest was held into the cause of the Explosion and the Coroner's Jury rendered the following verdict: "We, the undersigned jury, empannelled to inquire into the death of William Whitehouse and thirty two others, find from the evidence given that these men met their death by an explosion of gas on February 8th about 7.15 p.m. in No. 2 east level, No. 4 slope, 15 west off No. 1 slope, No. 4 mine Cumberland. Cause of explosion unknown." The result of the special official investigation into the disaster is not yet known.

**COAL MINE TO BE ABANDONED.**—The Western Fuel Corporation of Canada, a limited liability company, has been closed down and, it is understood, will be

pletely abandoned. This property is about three miles from the city of Nanaimo. It was opened some forty years ago and its initial operation was unique by reason of the fact that transportation was over an aerial tramway from the mine to Nanaimo Harbour, one of the rare instances of the use of such a tramway in connection with colliery work in Canada. Over a considerable period it was shut down and was developed a second time by the New Vancouver Coal Co., which since has passed out of existence. Once more its workings were deserted until the year 1916 when the Western Fuel Company took hold and so pushed work that the Herewood became during the war a considerable producer. It was at this time that it reached its peak in point of output, an average of 1,000 tons a day being mined and brought to the surface. In recent months the production has been steadily declining until finally it ran to only a few hundred tons a day. The Company evidently has concluded now that the economic life of the mine is at an end. The main haulage way of the mine was a little over a mile in length. Thus another of the well-known Vancouver Island coal mines passes into history.

**COLLIERY OUTPUT FOR JANUARY.**—The coal output of British Columbia for the month of January was 271,065 tons. Notwithstanding the competition of fuel oil and the practical prohibition of export to the United States because of the 53 cents a ton duty imposed by the Fordney tariff, the industry is holding its own. This only emphasises the possibilities were these handicaps to be removed.

To find the production of the Crow's Nest Pass collieries maintained at normal is both surprising and gratifying. There is no doubt that this field is hard hit by the two causes mentioned and yet the Coal Creek mines have not lost a day this year. Fernie coal is still being sold to the Great Northern Ry. and its popularity as a domestic fuel in the homes of the prairies is said to be increasing. Coke from the Michel ovens is being supplied to the Trail Smelter. That the industry is able to flourish in spite of adverse tariff and of stiff competition speaks well both of the quality of the coal and of the efficiency of the management.

At the Granby Collieries, Cassidy, where the management has been troubled with "blow outs", the January production totals 24,615 tons, the highest from any single island coal mine, with the possible exception of No. 1, Western Fuel Corporation. The Cumberland Mines of the Canadian Collieries (D) had an output of 23,180 tons during the month, the greater part of which, no doubt, came from No. 4 Mine where the recent explosion with heavy loss of life took place.

# GREENING'S

## WIRE ROPE

*It's Quality Pays*

Greening's Standard Crucible Cast Steel, Best Plough Steel and Acme Steel Ropes are made from wire specially manufactured and unvarying in quality.

All the wires are carefully tested for tensile strength, elongation and tension; all material that does not conform to the highest standard is rejected. Records of tests are kept for five years and there is no possibility of inferior material entering into these ropes.

Greening's Wire Rope, as used by Canadian Industry everywhere under all conditions, is proof positive of the fact that "quality pays".

Our data files are always at your disposal or write for catalog.

**The SYLVESTER  
Hand Car Motor**will save  
time and  
money for  
you

Can be attached to any standard hand car.

If you are already using pump or push cars on your surface tracks it will pay you to install this efficient outfit on them.

The extra work your men can accomplish and the time saved will soon pay for them.

We manufacture a complete line of hand cars — motor, pump and push types. Our equipment is in use on every railroad in Canada and giving excellent service.

Let us send a copy of our catalogue illustrating and describing our entire line.

**SYLVESTER MFG. CO., LIMITED**  
LINDSAY ONTARIO

The contributing factors in making good Wire Rope are. Men who know how. The best grade of materials. The most Modern Machinery. We have all 3 and are producing the goods. Give us a trial.

Let us send our catalogue on Wire Rope and Fittings. It is an invaluable reference book and contains many helpful ideas on the care of wire ropes and cables as well as information on the best kind of rope to use on all classes of work.

We also manufacture Wire Cloth for all purposes Perforated Metal Clothes Lockers.

# There's a Record of Performance back of ENDURANCE GRINDING BALLS

Endurance balls will reduce your Grinding Costs.

The long and satisfactory service they render is an assurance of more efficient and less expensive Grinding operations.

We manufacture Cam Shafts, Shoes and Dies that are equally reliable.

Prompt shipments.

## Canada Foundries & Forgings LIMITED WELLAND ONTARIO

# STURDINESS—

The ability to take hard knocks as well as to give them is possessed by SULLIVAN Rotators in a high degree.

Which is one way of saying that Rotators show unusually low costs for repairs under nearly all conditions.

They ought to, because they are built from drop forged steel billets and solid alloy steel bars, heat treated by processes developed in Sullivan laboratories, and ground to the closest working fits for air economy and drilling speed.

## SULLIVAN ROTATORS

—are all-around, one-man hammer-drills Six types of Rotators and two styles of mountings are in stock for you to select from

## As You Would Like It

WE have endeavoured to make our service ideal from the customers' viewpoint.

In every detail of the transaction, from the minute your order is received by us until payment is made for oxygen and acetylene supplied, your requirements are of first importance.

We supply oxygen and dissolved acetylene of the highest quality, in modern cylinders, light in weight yet rugged in construction, fitted with leak-proof valves; at the lowest prices obtainable.

This service is available for you immediately. Why not take advantage of it?

## DOMINION OXYGEN COMPANY, LIMITED

*Operating the Welding and Cutting Gas Division of Prest-O-Lite Company of Canada, Limited*

General Offices; 80 Adelaide St., East, Toronto

Distribution Points: Hamilton, Merritton, Montreal, Oshawa, Quebec, Shawinigan Falls,  
Toronto, Welland, Windsor, Winnipeg

## WHY YOUR NEXT AIR COMPRESSOR SHOULD BE AN *Ingersoll-Rand*

Few compressor installations involve exactly the same problems. Capacity, discharge pressure, regulation and type of drive are different in each case.

But, before any compressor is bought, you should know how much it will cost per cubic foot to compress the air, and how long you can be sure of freedom from breakdown and decreased efficiency. In other words, take into account the operating costs, and go back to the coal pile or switchboard.

Ingersoll-Rand Compressors are not only built to deliver the air cheaply but to deliver it when you want it. Whether it be for only 3 cu. ft. per minute or one of our larger reciprocating or turbine units of 10,000 cu. ft. capacity, the name Ingersoll-Rand on that compressor means reliable service.

The small Class "PRE-2" Compressor shown above is built in three sizes and is of the two stage, duplex, plate valve type, with completely water-jacketed air cylinders, enclosed dustproof frames and automatic lubrication.

Regulation is obtained by a "Free Air Unloader" permitting operation at one-half or full load. Although these machines have not the nicety of control of our larger and more expensive Clearance Control Types, they exactly meet the needs of those requiring moderate amounts of air and provide practically all the advantages of the two stage, direct-connected, electric motor driven type of compressor, at a price in keeping with the resources of the operators of small mining properties.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.         | Value.      | Year.         | Value.       |
|---------------|-------------|---------------|--------------|
| 1891 .. . . . | \$4,705,672 | 1906 .. . . . | \$22,388,383 |
| 1896 .. . . . | 5,235,003   | 1911 .. . . . | 41,976,797   |
| 1901 .. . . . | 11,831,086  | 1916 .. . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

## Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

THOS. W. GIBSON,  
Deputy Minister of Mines,  
TORONTO, CANADA.

# TO SAVE YOU VALUABLE MINUTES

during the busy hours of the all-too-short business day is the prime purpose of the **ELECTRICAL DIRECTORY OF CANADA.**

**Where Can I Buy** this electrical fitting or device? You will find the answer in **THE ELECTRICAL DIRECTORY OF CANADA.** It contains 350 pages and 1200 classified product headings covering the entire field of electrical products used in industry.

**Who Is The Sales Manager** of Blank & Co., Ltd.? The answer is in a special section of **THE ELECTRICAL DIRECTORY OF CANADA.** Contains concise information regarding the officers and lines dealt in for upwards of 250 manufacturers and distributors operating in the electrical and power field of the Dominion.

**Where Is Blank & Co's Nearest Sales Office?** The answer is in **THE ELECTRICAL DIRECTORY OF CANADA.** It gives the location and street address of each branch and sales office for practically every manufacturing and distributing company serving the electrical and power field in the Dominion.

**Who Can Do A Wiring Job For Me In The City of Blank?** **THE ELECTRICAL DIRECTORY OF CANADA** gives the name and address of more than 700 Electrical Contractors and Dealers throughout the Dominion; the favorably known firms in almost every locality of any size in Canada.

**Logically Arranged And Adequately Cross - Referenced** to make the information it contains readily accessible and to conserve your time.

CANADIAN AGENTS

**Jones & Glassco, Regd.**

MONTREAL, TORONTO.

O. W. Ludwig, Plant Superintendent of the  
Raymond Lead Co., Chicago, says:

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful—and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

**MAKE YOUR Idle Water Power Pay Dividends**

**IMPROVED KINCAID WATER WHEELS  
DEVELOP ECONOMICAL and EFFICIENT  
POWER FOR MINES**

The "KINCAID" water-wheels deliver the full theoretical power calculated from a given quantity of water from a stated head.

Using the best materials combined with careful workmanship results in the "KINCAID" being a water-wheel as near mechanical perfection as it is possible to make it. Let us demonstrate its possibilities to you.

## Serving the Mining Engineer

The usefulness of a bank can only be judged by the advantages its service affords you.

The Imperial Bank, having over 200 branches distributed throughout the length and breadth of the Dominion—some of them located at remote points—is in a position to serve the mining engineer in all things financial. You will find this Bank's service always near at hand.

At all branches of this Bank the same courteous service is afforded to depositors whether their account be large or small.

## NATIONAL RESEARCH PROBLEMS

The conference on research held in Ottawa last month was, as a conference, a very successful gathering, well calculated to consolidate the opinion of the participants and to elucidate for the public benefit the ideas of the leading authorities on research. These are the practical results to date; but much is to follow, unless we mistake the intention of those responsible for the conference. Action on a matter of such importance must be deliberate and well founded, and we have no doubt that such action will ensue in due course.

The establishment of a national research organization to correlate and supplement the existing agencies was approved, almost without question from the delegates. The exact form this organization should take remains to be determined, though its general lines are already clearly delineated. Besides fulfilling the functions of a Bureau of Standards and correlating (though not necessarily controlling) the efforts of existing research organizations, it must provide facilities for such research, both purely scientific and industrial, as is not already sufficiently provided for in Canada. Most important of all, it must provide for a study of Canada's problems in a comprehensive way, such as is now the duty of no department or institution, either public or private, and for the lack of which our country is suffering at present a loss whose dimensions few realize.

To make clear this last point, let us take a concrete example. Pulpwood is now being cut in Canada at the rate of four million cords a year. Mixed with the coniferous woods and the small amount of poplar used is a certain proportion of hardwood (birch and maple) and poplar that is not only useless, but is detrimental insofar as it tends to produce a second crop of its own sort in place of the more useful pulpwoods. This worse than useless wood comprises at least ten per cent of the forest growth and in certain districts is as much as fifty percent. It has even been proposed seriously to slash and burn this hardwood and poplar in order to help the growth of a second crop of conifer. Probably a million cords of this wood is now wasted annually.

How can this latent asset be put to practical use? At present it is everybody's job, and nobody's job, to solve this problem. There are distinct possibilities for the use of this wood as charcoal. A million cords of wood will make half a million tons of charcoal

There are numerous metallurgical uses for charcoal in large quantities, if it is cheap enough. Prior to 1914 charcoal from Canadian wood distillation plants was worth \$10.00 a ton at the plant, the by-products providing a further value. The two cords of wood required to make this ton of charcoal cost \$10.00 at the plant. It is obvious that charcoal could be made in favourable localities from birch and poplar by the old method of firing in turf-covered heaps at a less cost than \$10.00 a ton. If there were available in the same locality cheap hydro-electric power and minerals of the proper sort, we might have the basis for a successful electro-metallurgical industry. Such, for example, might prove to be the case round about Lake St. John, in Quebec, where there is abundant water-power capable of cheap development and a vast resource in wood and where a trifling amount of investigation has already disclosed some mineral resources of prospective value.

At present the metallurgist and miner, the pulp and paper specialist and the water-power engineer are working away, each at his own line. Any correlation of effort among these and similar workers is chiefly effected by chance, or by the good offices of a man possessed of financial ability combined with vision. Such correlation might well be made the business of a national research organization. Only by some such means can we ensure that opportunities for the use of our natural resources will not be lost for the lack of someone to delineate them.

## CONSTRUCTIVE PUBLICITY

Public misconception of the meaning of the mining industry is one of the principal clogs to progress. To the man on the street, mining is nothing but a sublimated gamble. The prevailing ignorance as to the significance of our mineral resources is alike deplorable and dangerous. The informed mining man who in any way helps to enlighten this Egyptian darkness is doing a real service to the community.

On another page we present some extracts from an address given by Mr. Arthur A. Cole, mining engineer for the Temiskaming and Northern Ontario Railway, before the Toronto Empire Club. It is unfortunate that space does not permit us to print the address "in extenso." However, the paragraphs that we do reproduce are pregnant with suggestion and inspiration.

For instance, in referring to the productiveness of

Cobalt. Mr. Cole points out that "the camp has produced at the rate of two tons of pure silver for every working day for 19 years, and at the present time is producing at the rate of one and three-quarter tons per working day." This is the right and assimilable form in which to present such information to the public. The ordinary citizen does not think in ounces, but the word "tons" means something to him.

Mr. Cole took special pains to impress upon his hearers the fact that Cobalt and the outlying silver districts, quite contrary to popular assumptions, are by no means exhausted. To emphasize this he quoted Mr. C. W. Knight, of the Ontario Department of Mines to this effect: "Mining will doubtless be carried on for generations either in or around Cobalt, or in the outlying areas of Gowganda, South Lorrain, Casey, Montreal River, and elsewhere."

As to gold production, Mr. Cole alludes to the fact that of all gold producing countries Northern Ontario alone is increasing her outputs. This has a significance all its own.

The projected extension of the T. & N. O. Railway is strongly supported by the facts and considerations adduced by Mr. Cole. That a continuation of the line to James Bay is warranted seems indisputable. The enormous total of undeveloped water power available in the region tributary to James Bay is impressive. But most impressive is the bald fact that in the few hundred square miles that form only a fractional percentage of the 2,000,000 square miles awaiting closer exploration, there should have been found such unexpected wealth.

The tenor of the address is buoyantly and rationally hopeful. Reasoning "a fortiori", Mr. Cole demonstrates that mining will be the foundation stone on which will be built the industrial future of Northern Ontario.

### MENTAL "SLOPPINESS"

Most of us, if we find our bodies getting out of condition, are apt to get greatly perturbed over the fact. We will take to golf, or go in for a course of physical culture, or resort to a scientific dietary, or what not. For we realize that our bodies are complicated pieces of mechanism, but that, while liable to get sadly out of order, they are, fortunately, amenable to proper treatment, in a large number of cases, at any rate.

But what about our minds? The mind is a more complicated affair than the body. It is liable to get not less badly out of order. Yet, happily, it is, perhaps, even more amenable to proper treatment. But to how many of us does it ever occur that our minds can get out of condition and require to be put in order? And yet the mind has its own organs just as much as the body—its invisible muscles and arteries and so forth. Some of these organs may be atrophied.

some starved, some out of shape, and so on. And a large proportion of those thus suffering are doing nothing to put their minds in order. They are the victims of chronic mental "sloppiness" — that is to say, they possess minds which are not doing the work that minds are capable of doing.

Some are conscious of this mental "sloppiness." Others suffer from it, but are unconscious of it. They may see the effect of it in their work, but they are ignorant of the cause. Yet the signs of the latter should be plain for all to read.

First, there is procrastination — the putting off until tomorrow what ought to be done today. This is a matter with regard to which it is very easy to deceive ourselves. The distasteful job is one that will be better done for waiting, we may argue. Or we require time for consideration before we can tackle it adequately. Or we are "too busy" to attend to it now. And so on *ad infinitum*. But, whatever the reason — or rather the excuse — that we assign to ourselves for our procrastination, the result is the same. The distasteful work is side-tracked, the easy work is given attention.

Then there is loss of interest in our work. Almost invariably — except in cases where the job is palpably too big for the man — this signifies lack of effort. For it is a difficult thing to lose one's interest in a job at which one is working with all his might and main. The man who is master of his work does not lose interest in it. But the man who has let his work master him is almost sure to do so.

Then there is want of "stickatitiveness" — the desire to change one's work. It is only by sticking at the work that we are doing, that we outgrow it — grow big enough for the larger responsibilities that larger work entails. "Distant fields look green," but the man who is always hankering after "pastures new" — who says in his heart that his work is all drudgery, while the other fellow's is colorful, interesting and free from grind—is mentally "sloppy."

Indeed, procrastination, loss of interest in our work, and hankering after change of work all are due to mental "sloppiness" and inefficiency.

There is one sure cure for mental "sloppiness"—concentration. Let the procrastinator, instead of giving the distasteful job the "go-by", go to it. Let the man who finds he is losing interest in his job ask himself whether he is doing his work to the limit of his ability; let him give an honest answer to the question, and then realize that we cannot get happiness out of our daily job, whatever it may be, without paying the price of the best work that is in us, and act accordingly. Let the man who desires change of work take to heart the lesson that it is only when he himself has ceased to grow that his opportunities look limited.

The late Mr. Chamberlain — than whom no man worked harder or more quickly — used to say that if he surpassed other men in any quality at all, it was in his power of concentration. And this faculty of concentration can be acquired and cultivated. Of course, it needs will-power — the will not only to begin, but to continue, to concentrate. But the more we will ourselves to concentrate, the easier it becomes to do so. An enormous percentage of us are, whether consciously or not, mentally "sloppy". Nearly all of us can cure ourselves of that defect if we will. But the remedy is within us.

Incidentally, it may be mentioned that one of the most effective aids to concentration at will is to be found in memorizing. That, indeed, is one of the best kinds of calisthenics for the mind. There are few mental exercises better than learning great prose or poetry by heart. Ten lines a day for two months — there is a concrete remedy for mental debility. For the chief, but not the only, merit of learning by heart as an exercise is that it compels the mind to concentrate.

### QUEBEC POWER FOR ONTARIO GOLD MINES

The encouraging developments in the new gold district of northwestern Quebec and the resumption of activity on some older prospects there whose value had never been tested, lends added point to the recent recurrence of the old suggestion that Quinze River power might be developed for the use of Porcupine gold mines. The Quinze River powers are 100 miles from Porcupine, 45 miles from Kirkland Lake, and 50 miles from the prospects in Rouyn township.

The falls and rapids at Devil Chutes, two to three miles from Lake Temiskaming, are capable of developing 36,000 horsepower from a 60-foot head. This power is privately owned. Above this there is available an additional 90,000 horsepower, which could be developed as two equal powers each under 74 feet head. All this latter power is still owned by the Quebec government, which is notably fair in its terms to genuine investors. A storage dam at the foot of Quinze Lake has made its large expense available for storage purposes, thus enhancing the natural power capacity of the falls below; and there are opportunities for using other large lakes farther up on the watercourse for additional storage when required.

The Quinze River, with its excellent waterpowers and its hinterland of 9,500 square miles covered with pulp-wood and timber, much of which grows on arable land, is sure to be a seat of industrial activity in the near future. Should the Ontario government continue to block the wheels of progress with its present hesitating policy with regard to the waterpowers on the Abitibi River, nothing would be more reasonable than the development of Quinze River power for use in the goldfields of Ontario.

### EDITORIAL NOTES

There is now quite a scramble at Matachewan in Northern Ontario. It is not like the scramble in Rouyn township in Quebec, where a winter rush is on; it is more like scrambled eggs. There has been a bewildering succession of stock flotations, reorganizations, mergers and consolidations, mixed up into a mass that it is hoped will be palatable for investors. We shall not attempt to unscramble the scramble. Some of the eggs are not strictly fresh, and besides we suspect that a "bad egg" is mixed up in the affair.

As we go to press, the Canadian miners from east, north and west, and visitors from the south, are gathering for what promises to be an unusually interesting and important annual meeting of the Canadian Institute of Mining and Metallurgy. We shall give a record of the proceedings next week.

### SAINT PETER AND THE LONE PROSPECTOR

A lone prospector lay a-dying;  
Wild round his hut the winds were crying;  
Soon came the racking throes of death,  
And he exhaled his final breath.

\* \* \*

As, winging fast through space, he flew,  
He felt uncomfortably blue;  
He wasn't confident what greeting  
Saint Peter would vouchsafe on meeting  
A fellow who had knocked around  
And sinned as men to sin are bound.  
Saint Peter spoke him with the air  
Of asking him what fetched him there.  
Saint Peter, also, when he found  
Him a prospector, froze and frowned.  
"Hold" quoth Saint Peter, "sirrah, steady!  
"I've got too many men already  
"From Cobalt and from Porcupine!  
"I cannot keep those birds in line.  
"I'd give my halo and my keys  
"To find myself relieved of these."  
The new arrival up and spake:  
"The bet is on, shake, Peter, shake!  
"Admit me and I'll guarantee  
"That in three days there will not be  
"One darned prospector left but me."  
"You're on," said Peter, "if you know  
"A trick like that, why, in you go."  
Well, sure enough, ere thrice the sun  
Had set, prospectors one by one  
Came rushing out of Heavens gate  
As if they feared to be too late.  
And, last, the new arrival came.  
Saint Peter gasped, cried, "What's the game?"  
Said he, "Saint Peter, I just told  
"These guys about a strike of gold  
"That had been made way down in II-II—  
"And now—I've told so many—well—  
"It only struck me just this minute—  
"There may be something really in it!"

\* \* \*

Thus, then, we see the reason why  
Prospectors, when they come to die,  
Find little comfort in the sky.

# Impressions of the Ottawa Conference on Research

By A. G. HUNTSMAN.\*

The Conference on Research called by the Canadian Manufacturers' Association met at Ottawa on February 20, 21 and 22. Five sessions in all were held, with the following subjects presented:— (1) work and plans of the Advisory Council for Scientific and Industrial Research; (2) work of the research branches of the Government departments; (3) research work of the universities and agricultural colleges; (4) work of the research departments of commercial firms; and (5) general discussion. It appeared that the manufacturers desired to learn what research was being done and planned in directions bearing upon manufacturing, either directly, or indirectly in connection with the fundamental industries, (farming, fishing, mining, and forestry), that provide the raw materials for manufacturing. It is intended to publish these data on research. No attempt was made to crystallize (either in resolutions or otherwise) the various views presented at the conference. It remains to be seen what use the Canadian Manufacturers' Association will make of the information concerning research that has been thus disclosed.

It was a distinct revelation to hear of the very extensive nature and the extraordinary variety of the research work being carried on in the Government departments (particularly the Department of Agriculture) and in the universities (particularly those of Toronto and McGill). It was not apparent that there was any duplication in this research work, although in several cases owing to there having been coöperation, the same work was reported upon by more than one body. There was, however, duplication in claims, each of several bodies claiming that it had killed the grasshoppers out west! This is reminiscent of the answers to the question of "who won the war."

No less important was the demonstration of the great length of the chain of work between the coming of a new idea and its actual application in the industries. New ideas came to light in the investigations in pure science in university laboratories, and these ideas form the starting point for further investigations. The varied facts and theories so provided are in part at some time taken up in the laboratories of applied science and their bearing on industrial problems more or less clearly demonstrated. Finally commercial firms take them up either directly or through their research laboratories and actually make use of them in industrial processes. If it is true that there is no royal road to learning, it is still more true that there is no easy road to industrial progress. Occasionally short cuts to improvements in processes are found, but almost always attempts to reach the goal by plunging blindly and at random end in failure. Sure progress comes by careful and thorough investigation of the subject from the most general and fundamental researches in pure science to the narrowly limited applicational research in connection with the manufacturing process.

It was made abundantly clear that it is neither possible nor desirable to limit a special type of research to any institution or kind of institution. While purely scientific researches are ordinarily carried on in the laboratories in pure science of the universities, nevertheless they are also done, and at times need to be done, in

applied science laboratories, in research branches of Government departments, and even in laboratories of commercial firms. Similarly for applicational researches, these may be done in any institution. For example, at McGill University in an investigation of the properties of hydrogen peroxide, it was found necessary to devise and apply new and special kinds of pumps. Research being in effect in exploration and discovery, it is not possible in any given case to be sure what will be found or where it can best be found. It is of distinct advantage to have any given problem attacked in different ways, either in different types of institutions or by different types of individuals. Usually, however, it is possible to state more or less definitely where and in what way a problem can be attacked with the best prospect of success.

There was general agreement at the conference as to the great need for the Central Research Institute, planned by the Research Council. This Institute is required to do for Canada the kind of work that is accomplished in the United States by the Bureau of Standards and the Mellon Institute. In these fields Canada is quite undeveloped and dependent on foreign bounty. Fear was more or less openly expressed that the Central Institute might hinder the research work of the universities and Government departments, but it was pointed out that no such result had followed either in the United States or in other countries.

## AUTOMATIC TEMPERING OF DRILL STEEL

A mechanism for the automatic tempering of drill steel has been invented at the East Rand Proprietary Mines, South Africa, where it has been in successful use for several months past. Steel of varying carbon content loses its magnetic quality at the right temperature for quenching, and advantage is taken of this fact to quench it automatically, thus avoiding the vicissitudes incidental to tempering by hand. The drills, each in a separate tube to protect them from the gases of the heating oven, are held against a steel plate at the back of the furnace by means of powerful magnetic coils behind it. A lesser tension on the other end of each steel serves to withdraw it as soon as it loses its magnetic quality and is no longer held to the magnetised plate, this being the proper temperature for quenching. It is claimed that uniformly good tempering and a notable saving in drilling cost have been effected by this means.

## NEW PHOSPHATE DEPOSITS

Beds of phosphate of prime importance have been located in Morocco, 100 miles south of Casablanca and are now being exploited by the French colonial government as a state monopoly. During 1922, the first full year of operation of the experimental plants, 80,000 tons of prepared phosphate was shipped. The deposits cover an area 45 miles long and from three to 20 miles wide and are composed of beds of fine sand, virtually at the surface, the richer beds containing 72 to 75 per cent. phosphate of lime. The deposits thus equal in richness and rival in extent the famous phosphate beds of Florida, which at present supply half the world's annual consumption of seven million tons.

## COBALT SILVER DISTRICT

Most of you have a pretty good idea of what the Cobalt camp has produced in the past, so I do not intend to bore you with statistics. It will be enough to say that since the discovery of Cobalt, in the fall of 1903, the camp has produced at the rate of 2 tons of pure silver for every working day for 19 years, and at the present time is producing at the rate of 1 3-4 tons per working day. You will perhaps be more interested in knowing what the silver district is likely to produce in the future, and I am glad to have this opportunity to correct a misconception that many otherwise well-informed people entertain. I venture to state that I could find a number of men in this very room who have the idea that the Cobalt silver district is worked out, and that silver mining in this area is not worthy of any further serious consideration. Let me quote you the opinion of Cyril W. Knight, Assistant Provincial Geologist, who has recently completed the most comprehensive and at the same time detailed examination of the area. Mr. Knight says "mining will doubtless be carried on for generations either in or around Cobalt, or in the outlying areas of Gowganda, South Lorrain, Casey, Montreal River and elsewhere."

The geology of the Cobalt Silver District is much better understood now than it was in the early years of the camp's activities and as a result of careful geological work, mining development is now carried on much more scientifically than formerly. A good example of this has recently been shown in the Keeley Mine in South Lorrain. Years ago rich silver veins were discovered on the surface of this property. Money was supplied by a bank manager, but after this money was spent, with indifferent success, the mine closed down, the promotor died, the bank failed, and the bank manager went to jail. The mine was sold for a song, and lay idle for several years. A mining engineer who had faith in the property after carefully studying the geological conditions, secured an option on it for English principals. Then the war broke out and little active work was done until after the signing of the armistice. It was not until within the last two years that the careful development programme began to reap the hoped for reward. Within the last few weeks a vein was encountered which now looks as if it would surpass in size and richness, anything previously found in the district. Considering the past record of the camp, this is no small boast. In one round alone \$100,000 worth of silver was broken down by the use of \$25.00 worth of dynamite.

Properties that have been closed down are being reopened and new producers are appearing so that instead of decreasing, silver production is actually rising. Only two days ago a small high grade shipment came out from Elk Lake, the first ore from this camp for years.

Considerable revenue was also obtained by some silver mining companies from the cobalt metal contained in their ore and the high price of arsenic proved a blessing to the refiners.

## Gold Area

Travelling north from Cobalt, a part of the rich agricultural "Clay Belt" is soon entered, which is traversed by the railway for 25 miles before the gold country is entered. Two belts of sedimentary rocks are found running east and west, one to the north and the other to the south of the height-of-land, and varying from 25 to 40 miles apart. Where these sedimentary rocks have quartz-porphyrysts or feldspar-porphyrysts associated with them the conditions seem favorable for the deposition of gold. In the northerly belt the Porcupine deposits have been located on the west, with the Croesus Mine and the Lightning River area on the east of the railway. In the southern belt the most important part so far developed is the Kirkland Lake area, with Matachewan gold district on the west and Larder Lake on the east. This belt extends well over into the province of Quebec so that its total length is over 100 miles.

We cannot say that this gold country is the most important in the world, but it is significant that while the productions from all other gold countries are decreasing, Northern Ontario alone is increasing. Last year the production in gold was \$21,000,000, an increase of 40 per cent over the previous year, and this production would have been still greater had hydro-electric power development kept pace with mining development. With an adequate supply of power, which now seems assured, further increases will be shown in the future, and it is likely to be many years before the maximum production is reached. By the end of this year there will likely be some 15 gold producers. Of these, ten are Canadian controlled and financed, four American, and I English, but this latter was first brought into production by Canadians.

The production last year of the McIntyre Mine was \$2,000,000, of the Dome Mine \$4,000,000, but the greatest of all and now in fact the greatest gold mine in the world, was the Hollinger with a production of \$12,000,000. Remember that this is new wealth added to the country, a large part of which finds its way into the business of the City of Toronto. You will thus begin to realize, if you have not already found out, **that the Mining Industry is the bed rock on which the business of the Nation is founded.**

If you will think of the silver industry of the Cobalt district as having many productive years ahead of it, and the gold industry of Porcupine and Kirkland Lake (with a present production of over 25 millions annually), as being only in its infancy, we will be ready to proceed north to the town of Cochrane.

## James Bay Extension

The present northern terminus of the T. & N. O. Ry. is at Cochrane, the junction point with the Transcontinental of the Canadian National Railways. With the intention of eventually reaching a port on tide-water on James Bay, the Ontario Government has awarded a contract for a 70 mile northerly extension, and already 40 miles of steel have been laid. But you will ask, what is the object of this extension and where is the business for it to come from?

The distance from Cochrane to Moose Factory following the survey line down the valleys of the Abitibi and the Moose, is 188 miles. The country traversed may be roughly divided into two parts, the "Clay

\*Mining Engineer for the T. & N. O. Railway Commission.

\* Extracts from an address delivered at Empire Club Luncheon, Toronto, Feb. 8th, 1923.

Belt and the "Coastal Plain," with an intermediate sandy transition area of about 25 miles.

### Clay Belt

The first 70 miles north of Cochrane crosses the "Clay Belt," and as this is similar to, and in fact part of the "Clay Belt" along the Transcontinental and south along the T. & N. O. Ry. the extension of the railway northward may be considered as part of the general plan of opening up the country for agricultural settlement, for which purpose we know it is admirably suited. The "Clay Belt" is well timbered, the most abundant tree as well as the most valuable, being the spruce, suitable mostly for pulp manufacture.

### Water Powers

The water powers are an important factor. Roughly speaking, there are at present on 6 rivers between the Transcontinental and James Bay, about 600,000 undeveloped H. P. Along the T. & N. O. extension there are 3 important falls on the Abitibi River.

|                                     |         |
|-------------------------------------|---------|
| At Mileage 11 Long Sault Fall       | 65 ft.  |
| At Mileage 44 Island Portage Fall   | 55 ft.  |
| At Mileage 70 Burnt Wood Rapid Fall | 60 ft.  |
| & Abitibi Canyon Fall               | 180 ft. |
|                                     | 360 ft. |

### Coastal Plain

The "Coastal Plain" is low and swampy, sparsely timbered with a stunted growth mostly along the waterways. By placing pulp mills at strategic points, such as at the mouth of the Little Abitibi River, pulpwood might be floated down for treatment at such points. The soil may eventually be opened up for agriculture, but much drainage would be required and a top covering of a foot or so of moss or muskeg would have to be removed. Good crops can be grown, as I can testify, having seen an excellent garden at Moose Factory the first week of last September.

Although agriculture, waterpowers, and the pulp and paper industry would undoubtedly supply a considerable volume of business for a railway, these would not be the main reason for an extension to James Bay. The fisheries, and general tourist trade will be important factors; but the mining industry is likely to prove, as heretofore, by far the largest revenue producer.

### Archaean Protaxis

Now let us take an inventory of what we actually know about the northern mineral area. Take a look at the geological map of North America. The area surrounding Hudson's Bay like a great horse-shoe is known as the Archaean Protaxis, composed of pre-Cambrian rocks, the ancient back-bone of the continent. The area covered by these rocks comprises about 2,000,000 square miles, of which only a few hundred have been worked over in detail. But what are the results of this detailed work? South of Lake Superior in a southern extension of these old rocks are the vast iron deposits of the Mesabi Range and the world famous copper deposits of Michigan. Passing north into Canadian territory, we find the largest known copper-nickel deposits in the world at Sudbury. Still farther north, the silver deposits of Cobalt, and the gold of Porcupine and Kirkland Lake have already been referred to. Surely such a start should convert the worst pessimist into a most enthusiastic optimist. Let me repeat, this is the record after working over in detail a few hundred square miles of the more accessible part of a total of two million square miles. The key to most of this vast area is Hudson's Bay. With

the possible exception of Northern Siberia, this is the largest unprospected area remaining in the world. No matter what your political color, I venture to guess that no one here would prefer the present government of Siberia to that of Canada or its provinces.

### Cost of Exploration

The expenses of prospecting in this vast territory have hitherto been almost prohibitive. Apart from this, also, the time consumed in going to and from the point where exploration was to be made, was in itself so serious an obstacle that only a few government exploration parties have penetrated the interior. The result was that even with government parties, where the necessary funds were assured, the only rational method of extending the length of the exploration season, in order to make the result at all commensurate with the expenditure, was to winter in the north so as to be able to take up the work without delay as soon as the spring break-up took place. With the railway completed to a point on tide-water, such as Moose Factory, it is reasonable to suppose that small steamers will be placed on this inland sea to look after the summer coastal traffic. Such craft should be sea-worthy and of considerable carrying capacity but of shallow draft. With such small steamers making regular trips on the Bays, a party could outfit at tide-water and be at almost any coast point desired by the middle of June. The party would then have a clear four months for exploration before it would be necessary to make the return trip. The cost should not be excessive considering the facilities provided. It will require only one good discovery to start the flow of fortune seekers into this great north land, and the area to be covered is so immense that many years must necessarily elapse before the mineral possibilities can be made known, even in the barest outline.

### Prospectors

The exploration of this almost limitless Northland will be undertaken by a very different kind of prospectors from those that flocked into Cobalt in the early days. The experience gained in the Sudbury, Cobalt, Porcupine, and Kirkland Lake camps will be invaluable when pushing farther north. The Ontario Department of Mines has done excellent work in keeping well abreast of exploratory work with accurate geological reports and maps. The result is that today the average prospector has a good working knowledge of the geology of the above-mentioned districts and is keenly alive to the value of acquiring all geological information available on the district he intends to investigate. This will make exploration much more effective, as time will not be wasted in unproductive areas, and work can be concentrated where geological conditions appear favorable. The old haphazard prospector will be superseded by a trained field man, familiar with the geological formations that are likely to be most productive. The element of chance cannot of course be eliminated but it can thus be greatly reduced.

### Flying Boats

Another factor that may materially assist in the exploration of this territory is the use of flying boats for the transportation of men and supplies and also in preliminary photographic mapping and geological work. Last September I had an excellent opportunity of testing the feasibility of using a flying boat for such work. Leaving Remi Lake, which is located about 60

miles west of Cochrane, we reached Moose Factory in 3 hours and 5 minutes, a distance of about 200 miles. The next morning, leaving the Moose River, we proceeded east 30 miles along the shore of James Bay to Hannah Bay, where we turned south and followed the West river for about 50 miles to Kesagami Lake. After making an examination of this lake, we returned to Moose Factory for lunch. In the late afternoon we returned to our starting point at Remi Lake, having taken in all about 33 hours to make the round trip. Actual flying time was 11 hours, covering a distance of over 600 miles. To make the same trip by canoe would likely have taken at least 30 days.

#### Possible Rivals

The only possible rivals to the T. & N. O. in making accessible these inland seas are the Canadian Pacific Railway and the Canadian National Railways.

The C. P. R. could build a line north from the east side of Lake Temiskaming, but this would mean an extension of about 350 miles, as against another hundred for the T. & N. O. Railway, the business at the Bay would also be cut in two, so that the proposition would be that much the less attractive. Under the circumstances, we may say that if the T. & N. O. is pushed through to the Bay, the C. P. R. is not likely to parallel it at least for several years.

The Canadian National Railways has a line running down the Nelson's commonly known as the Hudson's Bay railway. This line is completed to within 100 miles of tide-water. The last 120 miles of constructed line is now out of commission through disuse, landslides and floods, so that if required it

would practically have to be rebuilt. Moreover, it is generally conceded that the harbour at the mouth of the Nelson is unsuitable and that Churchill harbour will be chosen instead. This change of terminus will lengthen the line by another 100 miles, bringing the total length of line to be constructed to over 300 miles. Churchill harbour is 750 miles north west of Moose Factory, is well north of the timber line and has a shorter summer season. (Moose Factory is 100 miles closer to Toronto than it is to Churchill). The object of building this part of the Canadian National Railways was to cut down the rail haul on grain from the northwest. Do you think that the Canadian National Railways will complete a line that will add the cost of construction of 300 miles of railway to its capital account, in order to cut down its rail haul and lessen by a corresponding amount its gross receipts? It seems to me that this leaves the field open to the Ontario Government Railway alone.

#### Conclusion

To reach tide-water on James Bay and thus make accessible the mineral resources of this vast northern heritage is to my mind the main reason for the extension of the T. & N. O. Railway to James Bay. The benefits of such an extension would not be confined to the province of Ontario, for in the opening up of the Ungava Peninsula the Province of Quebec would be greatly benefited. And would not this be a fitting method of wiping out an ancient grudge, the English province of Ontario assisting in the opening up of the French province of Quebec, to their mutual advantage and benefit?

## The John Inglis Company

EQUIPMENT AND PRODUCTS OF THIS LONG-ESTABLISHED FIRM

The John Inglis Company, Toronto, is known by its products from coast to coast of Canada. Since its operations commenced in 1860 it has been turning out boilers, pumps and engines steadily and on an increasing scale, and these are installed in every part of the country. Few Canadians realize, however, the present scope of the company's operations. The following brief description of the plant today and of some of the work that has been turned out may serve a present need.

The late John Inglis had his first shops in Guelph, Ontario, and one still runs across many a sturdy old boiler with "Guelph" on the name plate. For almost thirty years the plant has been in its present location on Strachan Avenue in Toronto, and for twenty years the firm has been incorporated under the present name.

The plant today is housed in three large, modern factory buildings and a number of smaller ones. A large new boiler shop contains plant for handling plate work of the largest dimensions. A smaller boiler shop is equipped for light plate work and for welding. The machine shop is capable of handling a great variety of work large and small. These will be described in turn, and then some of their products. This description will allow the reader to gauge the capacity, both as to range and size, of the plant.

#### Boiler Shops

The large boiler shop has two bays, each 60 feet by 400 feet, and is served by four electric overhead tra-

velling cranes of 25 tons capacity with a 30-foot lift, as well as one tower crane of like capacity with a 50-foot lift. Large plate rolls are 14'-3" wide, and a large plate planer, 36'-9" between housings. The building contains a full equipment of punches, shears, hydraulic riveters, etc., all capable of handling plate up to 1½ inch in thickness and of driving 2-inch rivets. This outline of the equipment makes it obvious that there is very little plate work, either large or heavy, required in our modern industry that cannot be handled in this shop.

The smaller boiler shop, with bays 40 feet and 30 feet wide and 300 feet long, is equipped for light tank work and small boilers. It has two overhead travelling cranes, of 25 and 10 tons capacity and 28-foot lift, in the larger bay, and five small cranes, from 2 to 10 tons capacity, in the smaller bay. Beside the regular equipment for rivetted boiler and tank work, this shop has complete equipment for electric welding and oxy-acetylene welding. There is also available a portable electric welding equipment with independent oil-driven generator for use on work that cannot be brought to the shop.

An inspection of the work in progress in this shop gives one the key to the John Inglis reputation for thorough workmanship. Every workman is a craftsman, and meticulous care is the rule, not the exception. The foremen are "on the job" with their men at all times, and prevent mistakes instead of rectifying them. The staff, from the general manager down, are conversant to a surprising degree with the detail of

the work in hand and this of course is a very effective deterrent of shoddy work. Testing is rigid and is conducted faithfully.

### Machine Shop

The machine shop has two bays, 60 feet and 40 feet by 420 feet, the larger bay being equipped with two mechanical travelling cranes, of 25 and 15 tons capacity and 28 foot lift, and the smaller bay with one 10-ton crane with 17' 5" lift. Only the outstanding machines can be mentioned separately. A large boring mill has a swing of 16 feet diameter and is 7' 6" in height inside the housing. A large planer is 7' 8" between housings and has a table 20 feet long. If it is required to machine a piece of work too large to go inside the housing, this planer can handle it by means of an attachment. The work is fixed to surface plates in the floor, and a portable tool head is attached to the planer table, which thus machines satisfactorily the fixed piece to be worked. By this means there were machined lately both the seats and the gates of large Broome Caterpillar sluice gates for installation at the Lower Sturgeon Falls power plant on the Matagama river, near Timmins, Ontario. These gates have openings 14' 5" by 14' 6".

The largest lathe in the shop, which is really a marine engine crank-shaft lathe, has a swing of 50 inches and handles a length up to 28 feet. There is a hydraulic press for making press fits whose capacity is 300 tons.

3000 H. P. Triple Expansion Marine Engines,  
built for the 8000-ton Boats of Canadian  
Government Merchant Marine during  
1919-20-1921

The smaller machines comprise the following: 38 lathes, from 7" swing to 48"; 6 turret lathes; 4 milling machines; 3 shapers; 4 planers; 10 drills; 4 boring mills; 3 slotters; 5 grinders, and miscellaneous small machines.

### Flange Shop, etc.

The flange shop has a capacity in accord with the rest of the plant. There are two sectional hydraulic flangers of 150-ton capacity, for flanging plates. These are equipped with special 5-ton jib cranes of 20-foot

radius, developed in this plant as no suitable design could be found ready-made. There are also two four-poster hydraulic flanging presses of 300 and 350 tons capacity respectively, for the heavier work.

The blacksmith shop has, beside the regular equipment, Acme bolt machines and a steam hammer in which small drop forgings are handled.

The power plant is compact and effective. Hydro-electric power is used whenever possible. The machines are all equipped with electric drive, individual for the larger ones and grouped in the case of the smaller machines. There are 42 a.c. motors in all, from 3 to 200 H.P. The cranes are driven by d.c. motors furnished with power from a rotary converter in the power house, which also provides current for the electric welding.

Typical Small, Direct-Connected Turbine  
Pump

Steam is raised in the boiler plant by fuel oil for the steam hammers, for testing boilers and pipes and for heating the plant.

### Typical Products

From the above description of the plant's equipment it can be seen readily that it is capable of turning out an unusually wide range of products. The firm has, however, specialized along certain lines, and a description of some typical and outstanding products of the shops will serve best to show what can be done. The range includes steam boilers of all kinds; tanks; pipes and penstocks; pumps, reciprocating and centrifugal, large and small; steam engines, reciprocating and turbine; water turbines; marine engines. There

Boiler for S. S. "Rapids Prince," 14 ft. 8 in.  
diameter and 11 ft. 6 in. long.

are special facilities for heavy and large work. Contracts are executed to the customer's design, or designs and specifications can be furnished by the company's own engineers. Recently arrangements have been made to manufacture in these shops crushing, conveying and other special machinery formerly made in the United States.

#### "Rapids Prince"

In 1910 the John Inglis Company built the steamship "Rapids Prince," sub-letting the contract for the hull. This boat is 204 feet long and is equipped with two 4-cylinder triple expansion engines of 400 H.P. each, and a Scotch boiler 14'-6" by 11'-6". A feature of the construction is that the steel plating of the hull is covered with 3-inch oak plank, as it has been found by experience that the covering of wood distributes the shock and prevents perforation of the hull when the boat touches rocks, as is liable to happen in shooting the rapids of the St. Lawrence. There is no doubt that this precautionary measure in the construction accounted for the remarkable showing of strength of the "Rapids Prince" when she grounded in the Long Sault rapids last summer.

#### Blast Furnace and Gas Producers

In 1921 the firm built for the Canadian Libbey-Owens company, of Hamilton, three Camden automatic heavy duty gas producers to make gas for use in melting glass by their new continuous process. They are 10'-6" inside diameter and 17 feet overall in height. The outer shell revolves at the rate of one turn in 26 minutes, and inside there are water-cooled stirrer bars to break up clinker. The three producers gasify a 100 tons of coal per day.

The new blast furnace of the Steel Company of Canada at Hamilton, blown in a short time ago, was constructed by the John Inglis Company. A spare bell and hopper, 12 feet maximum diameter and 9 feet high, are just now being completed. The furnace is 90 feet high and of 600 tons per day capacity. It is furnished with a McKee top. The shell is of inch plate. The iron and steel work filled 45 railway cars as sent from the shops.

The new furnace replaces a smaller one built about 15 years ago by the same firm. The original stoves are still in use. The new furnace is one of the most effective on the continent, and is of maximum effective capacity for a blast-furnace.

#### Mining Machinery

The John Inglis Company now manufacture in Canada the full line of crushing, screening and handling machinery made in the United States by Chalmers and

Williams of Chicago. Notable among these are the Symons disc crusher and the Ross grizzly feeder, each of which marks a radical change in its field and a distinct advance in the practice of reduction. They manufacture also the well-tried standard reduction machinery — B. B. gyratories, jaw crushers, crushing rolls, ball, tube and rod mills, trommels, pulsating screens, stamp batteries and accessories.

Large Heavy-duty Jaw Crusher

There has been incorporated recently a new subsidiary company. Webster-Inglis, Limited, to make in Canada the wide range of conveying, elevating and power transmission machinery now made by the Webster Company of Tiffin, Ohio and Chicago.

The company also has arranged to make in Canada the Wellman-Seaver-Morgan specialties, and have already made hydraulic turbines of designs developed by that well known firm.

The principal officers of the John Inglis Company are, President and General Manager, Wm. Inglis; Secretary-Treasurer, C. H. Fierheller; Superintendent, J. T. Lewis; chief engineer, George Fax.

\* \* \*

All told, the John Inglis Company, by virtue of their mechanical facilities, their capacity for fine workmanship and the lines of manufacture they are prepared to follow out, are in an exceptionally favourable position to do their part in building up Canada's iron and steel industry.

Longitudinal Section of Symons Horizontal Disc Crusher

The discs on the right revolve together at 100 r. p. m., thus providing the centrifugal force that feeds and discharges the particles of rock. The lefthand end of the horizontal shaft is mounted in an eccentric bearing, which revolves at 150 r. p. m. in a direction opposite to the discs, thus causing the discs to open and close the small distance illustrated at the rate of 250 times a minute, and so causing the effective

## COAL AND OIL

### Imported Fuel Oil Cutting Into Market For British Columbia Coal—Import Duty Suggested

"Coal vs Fuel Oil" was the subject of a recent address delivered by the Hon. Wm. Sloan, Minister of Mines for British Columbia, to his constituents in the mining town of Nanaimo, Vancouver Island. In the course of a closely reasoned speech Mr. Sloan showed that the coal mining industry of his Province has not been advancing as have other enterprises dependent upon natural resources and increasing population for their maintenance. He argued that the chief reason was the admission to Canada of foreign fuel oil practically duty free, the tariff of one half cent a gallon being inconsequential. If the coal mining industry of the Canadian West, the basis of all industrial progress, to continue in a flourishing condition he asserted it would have to be protected, either by tariff restrictions imposed by the Dominion Government or a tax imposed by the Province on oil used within the jurisdiction of its Government.

Mr Sloan's address, in part, follows:

"I have stated that British Columbia has made marked strides in point of population during the past ten years. This naturally has applied, too, to business and all related industry and forms of activity. The lumber, fishery, and associated industries, have progressed. There however is one notable exception to the rule and the exception is found in coal mining. This statement may be thought to be remarkable and by some, perhaps, it will be doubted for the moment, but I propose showing it to be correct.

#### Progress in Metal Mining

"In metalliferous mining we have gone ahead by leaps and bounds in the course of the last twenty years. To convince you it is only necessary to submit figures dealing with the output of Zinc, Lead and Copper over this period. These will show that the advance has been commensurate with the growth in population. The figures follow:

| Year | Metal  | Production      |
|------|--------|-----------------|
| 1910 | Zinc   | 4,184,000 lbs.  |
| 1922 | "      | 59,000,000 lbs. |
| 1910 | Lead   | 34,000,000 lbs. |
| 1922 | "      | 48,000,000 lbs. |
| 1900 | Copper | 10,000,000 lbs. |
| 1910 | "      | 38,000,000 lbs. |
| 1920 | "      | 45,000,000 lbs. |

"During the war, owing to intensified demand, the production of copper went as high as 65,000,000 lbs.

#### Coal Mining Stationary

"A glance at the figures with reference to coal discloses a much different story. Going back to the year 1880 it is found that the output was 250,000 tons for British Columbia. In the following ten year period the progress was satisfactory, the production for 1890 being 678,000 tons. The same may be said of the ensuing ten years, the 1900 production reaching 1,435,000 tons, or more than doubling itself. The peak was reached in 1910, the end of the next decade, when the total production for the Province was 2,800,067 tons, or again almost double the previous 10 years figures. In 1920 we find that it had dropped to 2,595,125 tons; that there was a further decline in 1921 to 2,483,995 tons, while that for the last year, 1922, stands at about the same figure, namely, 2,559,414 tons.

"I quote these statistics to show that we have not been making the headway in the coal mining industry

that would be expected, that the steady progress that would come naturally to a basic industry such as this with an increase in population and in general prosperity has been lacking and that therefore there is something wrong, and that we, who are so much interested, should bestir ourselves in the determination to locate the seat of the trouble and having found it to apply an effective cure in the shortest possible time.

#### Cheap Fuel Oil Appears

"In 1910, as I have indicated, coal production reached its highest point and it is significant that shortly after this time the importation of fuel oil began to assume

HON. Wm. SLOAN  
Minister of Mines for British Columbia

considerable proportions into this Province. A tax of one-half cent a gallon was placed on fuel oil imported to Canada in 1916. I would point out here that the coal output in the year 1915 in British Columbia was only 1,611,129 tons, a very serious drop as against the 2,800,067 tons of five years before.

"The duty of one-half a cent on fuel oil I maintain has never been effective. While the price of such oil in the Province has fluctuated it never attained the point that permitted coal to enter into competition with it on anything like even terms until 1920-21, which period marked a greater advance in local quotations than any of which we have record. Now, once again, owing to the opening up of new wells and to the comparative slackness of foreign markets outside the continent of America, it is back at about \$1.25 a bbl. Estimating 4 bbls. as being the equal of a ton of coal, this means five dollars a ton coal. When we place this figure against the quotations on coal at world market bunkering centres the seriousness of the matter strikes

home. At New York on November 4, 1922, coal was quoted at \$7.90 and \$8.15 a ton; at Philadelphia at \$7.65 and \$8.15; at Hampden Roads at \$7.15; at Cardiff, Wales at 28s, or \$6.44 and 29s, or \$6.67; at Newcastle, Eng., at 27s, or \$6.21. Present prices at Vancouver Island ports are \$6.60 and \$7.00.

#### Higher Import Duty Proposed

"I may say further that the amount of fuel oil imported into this Province means the displacing of some 90,000 tons of coal a month on our markets. This is almost 75 per cent. of the present monthly production of the Vancouver Island Collieries. In other words, if there were no fuel oil the coal mines of this Province would be called upon to produce over a million tons of coal more than at present per annum. It needs no stretch of imagination to realize the results. There would be no slack times, the mines would be operating at capacity throughout the year, the coal fields would be developed on a larger scale than at present, employment would be increased, the payrolls would be larger, the currency circulated in our mining centres would be increased, prosperity would grow, not only in the colliery districts, but would radiate throughout every line of industrial endeavour having an effect in every community and in every section of the Province.

"And what has the one-half a cent a gallon duty accomplished? If it was intended to protect the industries with which the Fuel Oil competes it has failed miserably in British Columbia. If it was intended to materially swell the federal exchequer it has not registered a very complete success. The Dominion Government has collected in British Columbia through this one-half a cent duty since its imposition in 1916 — over six years — the sum of \$2,916,000 while in the last year, 1922, the income from this source was \$505,000. It may be said that this is not a mean sum. Considered alone, perhaps not. When placed alongside the revenue requirements of the Dominion and the possibilities of the duty if applied to really protect our coal mining industry, its insignificance becomes clear. A material increase in this duty! — that to my mind is the solution, that is the cure of the disease with which the coal mining industry of our Island is afflicted."

Continuing, Mr. Sloan pointed to the fact that the 53 cents a ton duty now imposed by the Fordney tariff, which is operating to check the export of coal from the Crow's Nest Pass and other collieries, is directly due to the 53 cents a ton duty levied on American coal as a protection to Nova Scotian collieries. Thus the West, he argued, is made to foot the bill for the East.

After alluding to the success of negotiations with the Dominion Government with respect to using Canadian coal on the vessels of the Canadian Government Merchant Marine, Mr. Sloan pledged himself to do all in his power to bring into effect an import duty, either federal or provincial, on fuel oil as a means of stimulating home production of coal.

#### LETTERS FROM READERS

##### Madagascar Graphite

To the Editor,

Canadian Mining Journal.

Sir:—

In your issue of the 16th inst., I note a letter from Mr. F. C. C. Lynch, of the Natural Resources Intelligence Service, Ottawa, relative to Madagascar graphite. It is possible that both Mr. Lynch's informant and myself have made slight errors or omissions.

My statement as to the unsuitability of Madagascar graphite for crucible making referred rather to the

United States, our logical market, than to the world generally though I still think the statement good. Unfortunately a great many of my data are in Toronto and I cannot, without loss of time, provide all the proof necessary to make my statement good at the present writing.

In a confidential report, printed for the Committee on Ways and Means, Washington, 1919, the statement is made:

"Recently, the French island of Madagascar has come forward as a rival producer of crystalline material. The quality of the product is a little different from that of Ceylon. *It is not satisfactory to domestic crucible makers, but is preferred abroad because of its low price*". (The italics are mine.)

Henry G. Ferguson, United States Geological Survey, "Graphite in 1917", says: "American crucible manufacturers prefer the Ceylon graphite to other grades".

Mr. Lynch says: "it (Madagascar) is being used in preference to Ceylon graphite owing to its better quality and grade". I have not the imports of Ceylon and Madagascar graphite into Great Britain for late years but am able to quote the value, per ton, of the imports into the United States from the two countries for the post-war years of 1919, 1920 and 1921 and they are illustrative:

| Year | Ceylon   | Madagascar |
|------|----------|------------|
| 1919 | \$161.90 | \$120.35   |
| 1920 | 117.05   | 60.80      |
| 1921 | 86.30    | 62.60      |

As the Ceylon material is crude and requires expensive milling while the Madagascar stock is finished and supposedly ready for the crucible maker it seems strange to me that the material of "better quality and grade" is so much the cheaper. It cannot be by reason of exchange as the Madagascar producers are, I suppose, business men and would rather take advantage of it.

Mr. Charles Pettinos, New York, one of the largest importers of both Ceylon and Madagascar graphite, writing of Madagascar in "Graphite in 1291", United States Geological Survey, says: "There are large stocks in Madagascar, France, England and America. It will be absorbed much more slowly than the Ceylon stocks".

Again, if the Madagascar material is "better in quality and grade", why is this?

For obvious reasons I cannot give the names of my informants here though I will gladly put the Intelligence Service in touch with them when they will find that insofar as the United States crucible makers are concerned, Madagascar graphite is eminently unsatisfactory. With few exceptions I know all the crucible makers on the Continent, more or less intimately, and they all condemn Madagascar graphite to me as being unsuitable because of the lack of uniformity, though not necessarily of carbon content. They find that, in the same batch of pots, one or more are very good and the rest are exceptionally poor.

While I naturally resent the last paragraph of Mr. Lynch's letter, wherein he says I am disseminating information "detrimental to the development of Canadian resources", I probably have to thank him for publicly bringing up the question. I will, with your permission, in the near future take pains to prove my point and at the same time enlighten the Natural Resources Intelligence Service, Ottawa.

H. P. H. Brumell.

Professors Carter and Hevesy of Copenhagen University have discovered in certain zirconium minerals a new element, much like zirconium, which they have

# Mine Timber

By J. A. McMASTER \*

The proper utilization of structural wood in the mining industry is an economic necessity. For too long a period, the writer believes, the buying of timber has been accomplished after merely consultation with a handbook showing comparative strengths. This is ideal for steel, but it is to be remembered that the weakness of timber is not generally in its inability to withstand a load but rather to resist decay. Most of the technical writing on timber deals with timber design rather than with the most desirable timber for use underground or for mill construction. This paper deals with the quality of mine timber, with application chiefly to Ontario.

## Spruce the Best Mine Timber

The initial stage of a mining property in Ontario sees the local round timber in use. Spruce is generally conceded to be the premier mine timber. Here, spruce is taken to include both the black and white varieties as they are rarely to be had separately. Both black and white spruce are found in the four eastern provinces growing side by side, similarly to red and white pine. No differences exist in the colour of the woods and, neglecting differences in bark, the chief distinction is that black spruce has a closer texture, indicative of greater strength, and has fewer loose black knots than the white spruce. This comparison is of interest as Nova Scotian coal companies used to require that 9 ft. props be of black spruce (and six inches in diameter at end.)

## Fir Principally Used

The answer to, "What timber shall we use?" would be more easily answered if Ontario's supply of spruce was as endless as fir is in British Columbia. The eastern supply of spruce together with all large timbers is very limited and the large sizes needed for mining supports are not available. Twelve-inch or larger round spruce is not procurable in quantity, hence the supplanting to-day of the round timber by squared manufactured stock from British Columbia.

According to Storms in "Mine Timbering," spruce is the choice of mine timber. Second place he gives to Oregon pine. Oregon pine and Douglas fir are synonymous terms. Douglas fir is available to order in practically any size and is stocked in sizes up to 24" x 24", and even lengths between 30 and 40 feet. Recently the Hollinger Consolidated has replaced spruce stulls by 12" x 18" fir sticks. The mines at Sudbury have used fir timbers for some time, Creighton standardizing on 12" x 12" with 6" x 8" in chutes. This adopting of standard sizes is commendable. The near future will likely see the Kirkland Lake and smaller camps using fir.

Fir timber will likely supply the mining market for the next decade and the vast forest reserves of British Columbia should be able to maintain the enormous demands with but slight advances in cost. Fir laid down in Ontario costs about \$50. per thousand feet. It is well to remember that one-half the cost of this product is freight and that this may be minimized by specifying (if your order can thus be placed) well seasoned or bone-dry stock. In the pur-

chase of timbers it is considered good practice by lumber concerns to establish a trade with a tried sawyer for the supply of straight-edged, properly dimensioned timber and to retain this connection. This should apply equally to mines. The vast difference in the product of one mill over another is the reason for advocating this policy. This brings forth the point that the initial cost is not the sound basis of valuating mine timber.

## Density the Best Guide

Specifications often call for "virgin growth", or second growth timber, yet the terms are without fixed significance, and material cannot be positively identified as belonging to one class or the other. "Virgin" or first growth means timber that grew up in a standing forest under conditions of active competition for sunlight and moisture. "Second growth" when applied to a forest stand usually means timber whose main growing period occurred under lessened competition after all or a portion of the original stand had been removed by cutting, fire, wind, or other agencies. In general "second growth" is associated with the idea of a second crop of timber. Virgin timber is the slow-growing timber while second growth, due to more favorable conditions, is relatively rapid. A faster rate of growth is evidenced by wider annual rings. These indicate stronger and tougher wood in the hardwoods, such as ash, hickory, elm and oak, but weaker and "brashy" wood in the conifers. Hence for strength, second growth is sought in hardwoods and virgin growth in the soft woods. As a second growth forest attains maturity, the rate of growth slows up and the annual rings may be no wider than in virgin growth of the same size. On the other hand, when a slow-growing, suppressed forest tree is freed by removing the neighboring trees it may grow rapidly for a long period. Therefore it is possible to have some wood with the characteristics of virgin growth and some with those of second growth in the same tree. Hence, strictly speaking, it would be better to disregard rate of growth and rely upon density as a guide to quality. Density is usually governed by a specification of the number of annual rings to the inch.

## Pine Timber

One of the chief reasons why spruce and fir stand out as mine timbers is because the sapwood and heartwood of these trees are about equally durable. This is not the case with the pines, as evidenced in the very sappy short-leaf or loblolly pines. It is worth while to explain here how to detect short-leaf pine from long-leaf pine, when this is possible. The latter is the hardest softwood and makes an ideal mill construction timber, and while not as desirable as spruce or fir for underground use, it may be used. Long-leaf pine will enter more and more into competition with fir in regard to cost, particularly in the smaller sizes. Short-leaf pine should not be used for any construction work without previous preservative treatment; but, strange to say, in squared timber it is not possible to determine visually one from the other. The strength of long-leaf pine depends upon the fact that it is a slow-growing tree compared with short-leaf pine, which sprouts up quickly. Hence long-leaf pine usually has the annual rings close together. In

\* Student in Mining Engineering, University of Toronto. Essay submitted to fulfil requirement of final year.

round timber it is possible to detect long-leaf pine by the diameter of the pith, that is, the core in the centre of the tree. If the pith is less in diameter than 0.1 inch, the material is long-leaf pine. To insure the purchase of long-leaf pine in manufactured timber, deal with a strictly long-leaf mill, such as Long Bell; avoid bargain sales by unknown companies. In small lots a safeguard is to specify the number of lines to the inch. This is generally placed at three to the inch.

### Rotting of Timbers

The life of timbers is very much affected by conditions in the mine such as whether it is wet, dry, damp, warm, cold; well ventilated and so on. This can be illustrated from personal observation at the Hollinger. Timber in the shafts and around the underground stations appeared to be in good condition. This location was continually wet, and in such a place fir or spruce will last indefinitely. In the main drifts where a constant supply of cool, fresh air passes constantly the timbers were not affected by dry rot or fungus; but in the crosscuts, particularly in the upper, older section of the mine where fewer raises exist and consequently fresh air is scarce, fungus had attacked the timbers and the further in from the drifts one went the more diseased timber was found. It was noticed that those stulls from which the bark had been peeled either deliberately or during the timbering, were relatively free of fungus. This is because the space between the bark and sapwood is a favorable place for fungus to grow. It is, then, at those sections where there is warm, damp, non-circulating air that greatest care in the selection of timber should be taken. It is conceded that uniformity in the system of timbering a mine should be adopted; but it does not follow that one grade should be used throughout. At the points where decay is the more likely, preserved timber or the best stocks available, properly seasoned and peeled, should be used.

### Care of Timbers

To season, timbers should be stacked for four summer months. This should give the timber the proper strength and endurance for mine use. Very often wet timber is placed in close piles where the circulation of air is prevented, and as the bark is continually wet we have the most favourable conditions for fungoid growth. With round shoot logs, stulls, or lagging, piles should be built in a crib fashion, using two to three logs as horizontal crosses every other tier. With squared timber, piles should be built on bottoms, the front of which should be slightly higher than the rear. Spaces should be left laterally between the timbers and if the material is not too heavy, cross timbers used. Where possible, cover with 1 inch culls. Such a pile should drain readily and the drying process will be very efficient and rapid. Creighton is one mine where shoot logs have been peeled and seasoned to good effect.

Fungus growth on timber is not in every case made up of fibre-destroying organisms, yet the appearance of fungus is to be regarded as evidence of the first stage of decay, as conditions that promote the growth of molds, blue stain fungus, and other non-injurious molds are usually favorable to the growth of the wood destroyers. Antiseptic treatment against these growths has been tried with fair success. Some of the chemicals used are sodium fluoride, borax, soda and cement, or the commercial product "gunite." The last, which is coming much into favour, is sprayed

on with a gun. Antiseptics in many cases are of little use, as decay is going on in places not exposed. Hence, pre-treatment of wood for these places should have been resorted to.

### Preservative Treatment

Four wood preservation processes are in use, and their respective adoption is based entirely on the increase of life of timber that is required, this increase being proportional to the degree of penetration of the preservative. These methods are:

- (1) By spraying
- (2) By painting
- (3) By open tank treatment.
- (4) By pressure treatment.

As a working basis, the life of untreated timber may be taken as 4 years. Methods 1 and 2 are said to give an increase of 2 to 5 years to timber; method 3, an increase of 5 to 10 years and the fourth increases the timber's life indefinitely. The cost of creosoting varies with every case and is dependent on the extent to which the treatment by any method is carried. Creosoting costs are not readily obtainable in Canada. A resumé of statistics in American practise places labour charges at \$2 per thousand feet. The labour need not be skilled for this work. In the open tank treatment, which is the more generally practised, the consumption of creosote is about 0.5 lb. per cubic foot. Creosote at 16c a lb. brings this to \$6.00 per thousand feet, or a total of approximately \$8.00, varying with conditions.

The practise of the Philadelphia and Reading Coal and Iron Co. is notable. Creosoting was first used by this Company in 1907 at Silver Creek mine using the open tank method and crude zinc chloride as the adsorbent. In 1909 they discarded this method for the more thorough treatment by pressure, and a plant was built for this purpose. More recent development at this property saw the replacement of zinc chloride by silicon fluoride which is slightly less costly and for treatment with which but 0.3 lb. of preservative is used per cubic foot. It is claimed to have a greater toxic effect than creosote. A preservative should be fire-resistant. Creosote may be so, but it brings in the alternative evil of fumes in case of fire. The coal industry has in general applied preservative treatment more than the metal mines and the above illustration is significant in that it shows how the use of pre-treatment has grown as it proved economical in that industry.

Sapwood will absorb preservative to a greater depth by dipping than will heartwood, and for this reason round timbers are preferable for creosoting to squared. Jack, loblolly or short-leaf pine, relatively cheap varieties of timber, lend themselves to preservative treatment as well, if not better than, fir or spruce. Costs of preserving dry timbers are much less than with green stock as it takes less time and it is easier to replace air in the outer cells than moisture. To pre-treat green timbers, slow pressure treatment has of necessity to be resorted to for good results. Many mines have begun actively the "drawing" of mine timbers from worked-out sections of the mine. After seeing some of these salvaged timbers and comparing them with creosoted piles resurrected near Niagara Falls, the obvious conclusion was that for this to be an economic policy, pre-treatment in the first place is necessary.

So far these remarks have applied more to timber than to planking. The use of 2 or 3 inch plank wider

than 10" or 12" practically means the use of western fir. It might be well to state why such plank from the west on delivery is less in thickness than the even inch called for. A rough joist 2 inches thick from the east will stand up to 2 inches by the Ontario standard. The Western standard is  $1\frac{3}{4}$ " and they base their sales on this. Plank from the west are shipped sliced or planed to this even thickness. Plans should conform to this to avoid extra cost. For planking of smaller sizes, local spruce, various pines and a limited supply of tamarack is available. A good lumberman's rule or axiom regarding grade of plank is "When in doubt use good white pine." Creighton mine in 1920 was using a considerable amount of 2" x 10" white pine, No. 1 box or common, to a dressing grade. Lately the market has seen an influx of jackpine and spruce, mixed, from the far north and east. Most of this jackpine is saturated with "red horse" streak, which on drying turns to dry rot. This can be bought cheaper than hemlock in sizes 2" x 4" and 2" x 6" and may find a limited use in wet places or by virtue of pre-treatment, in mills, or underground as plank between rails, etc.

#### Tips for Buyers and Users

Selling experience in lumber permits me to say that money often could be saved a buyer if he were made conversant with the available stocks as they are to-day, rather than as they were where he last made inquiry. Such neglect on the part of buyers may cost money, as it is not always the aim of a salesman merely to unload stock. With this point in mind I may say that the overhead cost of handling plank could well be reduced by the use of planing-mill machined lumber. The cost is not large, not more than \$2 per thousand feet. The reduction in freight often would repay this. For instance, a shaft now wet could be made water-tight by the use of shiplap or plank grooved for a hardwood spline. The latter would make a shaft practically proof against leakage while the former is so readily laid that why it has not been universally used, I am at a loss to know. The

side exposed most to weathering need not be dressed. This use of shiplap would insure a finished job in shaft timbering that is lacking to-day, at practically no additional cost. In fact, I believe that laying the plank would be so simplified that a net saving would result. Most mines have as an adjunct a small wood and timber shop. The installation of a planing mill and timber machinery is wholly dependent upon the size of the property. As the machines run only now and then, they often do not mean a business return and are merely for handy use. The buying of lumber already manufactured should be more economical.

#### Specifications for B. C. Mine Timber

The following grading of mine timber is given by the British Columbia Lumber & Shingle Manufacturers, Limited: No. 1 Fir mine timber to be free of serious shakes, splits, or rot. Will allow variations in sawing, sap stain, solid heart, and stain extending over not more than half of piece. Permits large knots and a few well scattered worm holes and wane, 3 inches on one corner or its equivalent on two or more corners. Will admit 15 per cent hemlock.

This specification appears loose and has been, I should say made by lumber men rather than by mining men. One point, the inclusion of solid or box heart, is noteworthy, as this is really desirable for mine timber. The greater part of construction timber is later resawn by planing mills and for this purpose quartered sticks are preferable. But where sticks are used whole, as in mining, the box heart has many good features. Besides its strength, it minimizes the number of timbers having slashes off their edges. The establishment of trade with reliable firm permits them to sort such sticks for mine use, to a specification.

In conclusion, it may appear that I am pushing economy beyond practical limits in the matter of timber; but, the utter lack of a sense of value shown by most mining men when buying lumber prompts me to say that if they will pay more attention to these and kindred details, it will prove of great benefit both in economy and in general mine maintenance.

## News and Comments

BY ALEXANDER GRAY

### WRIGHT-HARGREAVES IN 1922

It is no disparagement of other producing gold mines of Northern Ontario, to attach exceptional interest to Wright-Hargreaves Mines and their economical plant. Harry S. Denny, C. B. E., M. I. M. M., of London, South Africa, Australia, Mexico and at large, during his recent flying survey of the North Country, formed the opinion held by those most familiar with Ontario mines and mills, that the Wright-Hargreaves has combined efficiency and simplified milling methods comparable with the best.

If the slightest criticism has to be lodged against Wright-Hargreaves costs, it applies to the inevitable administration and Management item: \$0.540 per ton upon the small tonnage milled. Otherwise the operating charges are well balanced, the total of \$6.317 per ton milled conveying its own commendation of the management. That cost includes extensive Development and Exploration, Depreciation of Plant and Equipment. Apart from General and Undistributed Charges, the per ton milled cost was \$4.85. It is comprehensible,

therefore, why President Cabana was glowingly complimentary when he wrote:

"We have a most excellent plant and outfit. The construction work is all of the best, and as I reflect upon the progress of the development of our property and the erection of our mills and other buildings, I cannot see that a single mistake of consequence has been made, and that with the exception of some very minor details and adjustments, the mill is not only treating ore up to our expectations, but is exceeding them as previously indicated".

This, by way of retrospect, is reinforced by the further forewords of President Cabana:

"As we proceed in our operations and in the development of our property, I believe it will soon be necessary for your Directors to give consideration to the matter of increasing our mill to about double its present capacity, but this can better be determined after we reach the 1000-foot level in our present sinking operation".

Without dilating on the mining position, the manner

in which Mr. Cabana disposed of the company's plans for expansion is an exhibition of confidence awaiting verification. Such anticipations as Mr. Cabana indulges in bespeak continuance of the trust vested in the administration and management. It is almost a matter of mere petty cash to specify the cost of administration where there is manifestly scrupulous and capable control.

General Manager Wende has earned the respect entertained for him by all who know what he has constructed upon a foundation more experienced builders would not risk. With the Wright-Hargreaves and Sylvanite, he and his colleagues have the basis for greater doings. Were it not for this, something might be sought in the shape of estimated ore reserves.

Shareholders may trust their speculative investments with executives who have a model enterprise of its kind and who declare it to be their policy "to distribute all free surplus after making ample reserves for depreciation and depletion". Against current assets of \$274,125.44 on December 31st., the current liabilities were \$108,414.02. The balance of \$6,423.87 to the credit of free surplus has a working capital offset of sufficient in cash and cash assets for the purposes of the company. That the mining and exploration position is being protected, is indicated by the summary of development and exploration—

|                       | Shaft<br>Drifting<br>Feet | Cross-<br>Sinking,<br>Feet | Diamond<br>Cutting,<br>Feet | Diamond<br>Drilling,<br>Feet |
|-----------------------|---------------------------|----------------------------|-----------------------------|------------------------------|
| In Fiscal Year, 1922  | 2548                      | 445                        | 310                         | 827                          |
| To December 31, 1921  | 3315                      | 1155                       | 368                         |                              |
| Total at December 31, | 5863                      | 1600                       | 678                         | 827                          |

Of the 1922 development and exploration cost, amounting to \$86,095.27, and its relationship to the bullion production, it is to be noted that the total of preliminary cost development is written down to \$200,834.83. Most of the drifting during the year, was done on the 400 and 500-foot levels, and Mr. Wende reports that over three fourths of this, or 2977 feet, was in ore. Besides this No. 3 shaft was carried down from 420 to 865 feet, and stations cut at the 550,700 and 850-foot levels, together with the provision of a sump and pumping facilities at the 700-foot level.

Precedence is given to the work underground, because the present situation is so satisfactory that it is more to the point to follow new development and the implied promise of the President as to the larger mill. The present mill had an estimated capacity of 160 to 175 tons per day, whereas it averaged last year 205 tons, with a surprisingly small crew. Had it not been shut down for repairs and a power failure in October on account of the bush fire, the tonnage treated would have made an even better showing. As it was, the mill ran 88.31 per cent. of the possible running time, treating 66,181 tons for a gross yield of \$762,752.84, the average grade being \$11.52, the net profit per ton over all being \$5.20. On the current milling basis there was six months' broken ore supply on December 31st. With a larger mill, the ratio of profit ought to be increased. Meanwhile \$412,500 was distributed in 1922, and \$68,750 in Jan. 1923.

### ASBESTOS CORPORATION OF CANADA

The Eleventh Annual Report of Asbestos Corporation of Canada for the year ended December 31st. contains nothing to create misgivings in the minds of shareholders and conveys concrete information as to the financial position and prospects. Complacency is engendered by this statement:

|                                                    |                |                       |  |
|----------------------------------------------------|----------------|-----------------------|--|
| Investments:                                       |                |                       |  |
| Dominion Government Bonds ..                       | \$1,354,861.66 |                       |  |
| Company's Own Bonds and other Securities ..        | 853,624.66     | \$2,208,486.32        |  |
| Current Assets:                                    |                |                       |  |
| Inventories of Asbestos, Materials and Supplies .. | \$836,747.09   |                       |  |
| Accounts and Bills Receivable ..                   | 318,327.71     |                       |  |
| Cash ..                                            | 451,875.78     | 1,606,952.58          |  |
| Deferred Charges to Operations ..                  |                | 32,345.26             |  |
|                                                    |                | <u>\$3,847,784.15</u> |  |
| Current Liabilities:                               |                |                       |  |
| Accounts Payable and Payrolls ..                   | \$131,490.92   |                       |  |
| Accrued Liabilities ..                             | 2,513.61       |                       |  |
| Dividend Payable Jan. 13, 1923 ..                  | 115,000.00     | \$249,004.53          |  |
| Reserves:                                          |                |                       |  |
| For Contingencies & Gov. Taxes                     |                | 227,157.74            |  |
| Surplus:                                           |                |                       |  |
| As per Statement Attached ..                       |                | 2,211,076.94          |  |

A liquid position of that sort at the end of a period of trade adversity and international cross-purposes provides nothing more lugubrious than this, which is incorporated in a review of the history of the Asbestos Industry:

"Like all industries, the Asbestos Industry suffered a depression after the War, and during the past year the demand has been quiet, in spite of the drastic cut in prices, especially in the higher quality of grades, which had to meet Rhodesian competition as well as the small demand for this quality of material. In the lower grades, in which Canada stands pre-eminent, indications of a better demand are in sight, though prices are much below war prices. The European demand, which prior to the War purchased about 40 per cent. of Canada's output of all grades, is naturally very much curtailed, but in time the export business to Europe should improve, and given a sympathetic help from the Quebec Government, instead of a drastic short-sighted policy of taxation, the Asbestos Industry will eventually come into its own.

"Asbestos is supplied principally from Canada, Rhodesia, South Africa, the United States and Russia. The output of Canada more than equals the rest of the countries, and the quality of its higher grades is unexcelled."

Net working capital being \$3,517,316.77, the outlook being somewhat clearer, "all mines and mills are running at full day shifts."

Profits from last year's operations, after providing for Government Taxes, but before making provision for Exhaustion of Minerals, amounted to \$756,644.69, as against \$727,093.74. To this, \$136,414.08, the interest on investments and bank balances, was added, making the total \$893,058.77. After deducting for Bond Interest, Exhaustion and Depreciation, the net profits were \$543,258.63. This was ample to cover dividends on the Preferred and Common Stock issues and leave a surplus for the year, of \$83,258.63.

President W. D. Ross submits that the results "should be considered fairly satisfactory." Of the outlook, Mr. Ross says:

"Renewed building and commercial activities in the United States have been felt in the Asbestos Industry, and the demand for your Company's products has been greater than for the last two years. Offsetting this, however, has been the curtailed shipments to Europe, more especially to Germany."

During the year the stripping of ground at the King's Hill was continued, over 134,000 cubic yards having been removed, greatly enlarging this important pit and placing the Company in a position to increase its output when conditions warrant it. In connection with this property, plans have been carefully studied with a view to the erection of an additional Mill of 1,200 tons capacity per shift, which, when fully completed, will be nearly double that of the present mill. It is expected, with the experience gained in the past, the process of manufacture will be improved and economies result from the same."

### OPPORTUNITY IN SASKATCHEWAN CLAYS\*

The attention of those interested in Canadian raw materials for clay product industries in Canada has for many years been directed to the extensive clay belt known to extend over a wide area along the Weyburn Branch of the Canadian Pacific Railway in Southern Saskatchewan.

Owing to the nature of the clays in this field and their convenient situation as regards transportation, it has frequently been predicted that Saskatchewan will eventually take up an important industrial position in the Dominion based on industries utilizing clays, coals and natural gas.

Data on the Saskatchewan clay deposits has until recently been somewhat general, but steps have lately been taken to acquire more specific knowledge of the various beds, their suitability for a variety of clay products, and accurate investigations have been made with the ultimate object of placing before those interested such information as may lead to practical development.

A course at ceramics was instituted at the University of Saskatchewan to ensure a staff of experts for the future industry and a ceramic engineer secured who had a wide practical as well as theoretical experience. Private prospecting has supplemented government efforts, and to-day reliable information on the Saskatchewan clay deposits is so extensive and at the same time so encouraging as to warrant the closest attention from manufacturers and investors.

#### Readlyn-Willows and Eastend-Ravenscrag Deposits

So far the surveys carried out by the Province's Ceramic Engineer have resulted in concentrating attention on the deposits in the Readlyn-Willows and Eastend-Ravenscrag districts, these surveys having disclosed in these territories very large deposits of commercial clays. There are present in the district clays of a wide range of physical properties which permit of close control in body mixtures. In the immediate vicinity of Eastend there are at least two large deposits, easy of inspection, from which not only tests have been made, but many carloads shipped to Medicine Hat, Alberta, and manufactured into creditable and extensive lines of crockery and stoneware for the Eastern Canadian market.

In the Readlyn-Willows district the clays have been found to be of the ball or semi-ball types burning nearly white. In some cases a creamy white burning clay was found much lighter than similar commercial clays of Great Britain and the United States. These clays should form the basis for the manufacture of such lines as granite ware, floor and wall tile, insulators and similar ware where a white body is desired. There is also to be found in this district clays of the

stoneware type as well as semi-refractories suitable for screw-pipes, terra-cotta, enamelware and ordinary fire brick and stove linings. In the Eastend-Ravenscrag district the clays are of the earthenware and stoneware types, highly suited to the manufacture of Rockingham yellow ware and a wide range of stoneware, including chemical.

### Excellent Transportation Facilities

These two Saskatchewan clay deposits are arousing particular interest at the present time owing to the recent completion of the railway from Weyburn, Sask., to Lethbridge, Alberta, thus providing the final link in the transportation chain between these points. These deposits, which lie close to the railway line and not very far from the international border in South-Eastern Saskatchewan, are now provided with excellent transportation facilities. The Readlyn-Willows deposit is, in addition, within relatively short distance of the Souris coal fields, and the Eastend-Ravenscrag deposit in addition to being well located in the matter of a supply of pure water, is in close proximity to the great semi-bituminous coal fields of Southern Alberta. The completion of the railway line would seem to remove the one possible handicap to the exploitation of these deposits, and the many advantages should now render their development attractive investments.

The establishment of an extensive clay products industry in the Province of Saskatchewan in the not distant future, can be reasonably expected. Excellent clay deposits of every variety are available, with fine transportation facilities and in proximity to supplies of coal and other requisite materials for manufacture. These clays have been proven the equal of deposits anywhere, and exhaustive tests made in the ceramic laboratories of New York all gave eminently satisfactory results.

Saskatchewan is the logical home for such an industry in Canada. There is a constantly growing market for building material such as brick, tile and terra-cotta and great market possibilities for stoneware and even table ware. The Province of Saskatchewan alone imports heavily of these commodities each year. The existing industry in Canada is totally inadequate to supplying domestic requirements, and in the last fiscal year the Dominion imported clay products to the extent of \$10,781,592 as well as clays of various kinds to the extent of \$672,782, and such importation is on the increase rather than otherwise. Certainly there is a splendid opportunity for the investment of capital in the clay-working industry in Saskatchewan.

Due to high wages and short hours in the coal mines, high railway rates, and high wages in the iron mines and at iron and steel works, the steel trade of Britain is in a precarious condition. The cost of coal is 77 per cent above that of 1913 and railway charges are up 73 percent, whereas the present price of steel is only 13 percent in advance of 1913. The production of pig-iron in 1922 was 4,000,000 tons, against 2,600,000 tons in 1921 and 10,000,000 tons in 1913.

Sulphur is one of the very few commodities that is cheaper now than before the war. This is wholly due to the production by the Frasch method with hot water from the sulphur "domes" of Louisiana and Texas. The companies operating there are searching continuously for new uses for their sulphur, since the possible output of their deposits is much larger than the present demand.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## BRITISH COLUMBIA

**PORTLAND CANAL.**—An examination of the Fish Creek Portland Canal District properties of the American Mining & Milling Co. has been made by G. T. Jackson, formerly manager of the Alaska-Gastineau mine at Juneau, Alaska. Mr. Jackson was accompanied by W. R. Tonkin, vice-president of the Company. He is quoted as stating that these mineral claims should be developed by means of a longeross-cut tunnel, the ore being brought to the wagon road by tramway. The tunnel proposed will be between 1400 and 1500 feet in length, cutting at depth the entire vein system. The tram line has been surveyed and sites obtained for the terminals. A location also has been selected for a concentrating mill it is proposed to instal.

**TRAIL ORE RECEIPTS.**—Ore shipments to the Trail Smelter, Canadian Consolidated Mining and Smelting Co., for the week ending February 14th totaled 8096 tons. Three new 1923 shippers were the Ruth, Sandon; the Standard, Silverton; and the Nip and Tuck, Windermere. Following are the detailed shipments for the week:

| Mine                      | Tonnage |
|---------------------------|---------|
| Black Rock, Northport Wn. | 42      |
| Bosum, Silverton          | 32      |
| Company mines             | 6983    |
| Knob Hill, Republic Wn.   | 164     |
| Lone Pine, Republic Wn.   | 323     |
| Nip and Tuck, Windermere  | 30      |
| Paradise, Windermere      | 46      |
| Quilp, Republic Wn.       | 55      |
| Ruth, Sandon              | 40      |
| Silversmith, Sandon       | 237     |
| Standard, Silverton       | 81      |
| Steel Gp., Brisco         | 34      |
| Surprise, Republic Wn.    | 103     |

8096

**TELKWA.**—The Dome Mountain Mines, near Telkwa on the Grand Trunk Pacific Ry., are reported to have been acquired by the Federal Mining & Smelting Co., the negotiations having been conducted by T. E. Jefferson, in New York. Development, it is said, is to be started without delay. Henry Lees has arrived to take charge of this work.

**SMITHERS.**—James Cronin, of Spokane Wn., well-known as a British Columbia mine operator, is said to have sold the Babine-Bonanza Mine, upon the development of which he has been engaged for several years, to Messrs. Woods & Taylor of Fernie. This property is situated near Smithers, northern British Columbia.

**OPTION ON DOLLY VARDON.**—Mr. W. J. E. Taylor, of the Taylor Mining Co., is reported to have been given a year's option for the sale of the Dolly Vardon and Wolf Mines, Alice Arm. This has been granted by George Wingfield and Associates. If Mr. Taylor succeeds it is expected that he will be able to discharge

his company's liabilities in full. Under the circumstances it is regarded as doubtful as to whether the Dolly Vardon will be operated this season.

## NOVA SCOTIA

**FIRST AID.**—An improved type of stretcher is being used at the Cape Breton collieries this winter for the first time. It is intended for hospital ambulances only. The general comments of colliery physicians and hospital matrons is most favorable. The patients who have had occasion to use it loudly acclaim its merits. The Coal Company and the miners have been looking for just such a stretcher for a long time, and they are fully satisfied that they have now something that meets their requirements.

With the two large colliery hospitals situated at Glace Bay, a distance of from eight to ten miles from the farthest collieries on either side, much discomfort was experienced and delay caused to sick and injured patients by bad roads at certain seasons of the year when they were almost impassable. The Dominion Coal Company had purchased and fitted up ambulances to con-

The McKinnon Shock Absorbing Ambulance Stretcher Carrier.

vey the injured workmen and members of their families, in case of serious illness, to these institutions. But even with these it was felt that something better was necessary than the stretcher in use, although it is the latest American Army type. As is commonly the case, the man arose for the occasion and one of Cape Breton's

own sons, John F. McKinnon, showed himself equal to the task of making a stretcher that absorbs all the jolts and jars caused by bad roads. It is called the Shock Absorbing Ambulance Stretcher Carrier. It consists of a lower rigid frame that supports on shock-absorbing springs an upper frame upon which a stretcher is placed and fastened, the whole device being secured to the floor of the ambulance.

The device is light enough to be easily handled and is strong enough to withstand the long journeys over bad roads. It is just the thing needed at the collieries or any other works where industrial casualties of sick patients have to be carried any distance. Where the roads are good, the use of the stretcher almost eliminates the sense of motion.

The Dominion Coal Company, realizing the fuel value of the invention, were quick to adopt it and put it into service throughout their large colliery districts. The maker has registered his stretcher in Canada and the United States.

**DAMAGE TO STEEL PLANT.**—More damage was done at the steel plant and coke ovens Sydney during the short strike that took place there than is openly admitted. Yet it is due to the concealment of such things that the public remain ignorant of the gravity of the case, and the body of public sentiment necessary to prevent a recurrence of such acts is not permitted to form and function in the interests of good industrial conditions and trade stability.

**ACTIVITY IN EDUCATION.**—At no time in the Glace Bay has such interest been taken in adult education as at present. The Technical Schools have an attendance of one hundred and forty, and this would be much greater if more teachers could be provided. The People's School has over three hundred on its roll. This

school is being conducted by the St. Francis Xavier College, Antigonish, and many subjects are taught. Mining and Engineering schools are also helping to attain the standard of education aimed at by the miners of this town. At each of the mining and engineering schools, in the colliery village, First Aid classes are being carried on.

### FUEL BRIQUETTES IN 1922

A new record of production of fuel briquettes in the United States was established in 1922. Reports to the United States Geological Survey show that the total output was 619,425 net tons against 398,949 tons in 1921. In comparison with 1920, the year in which the previous maximum was attained, the increase was slightly over 9 per cent. Production in all districts in 1922 was larger than in the year before, the principal increase occurring in the Central States. The chief factor in the improvement in that territory was the increased demand for briquettes to make up the deficit in domestic anthracite in the region supplied from the Upper Lake docks. The total value was \$5,444,926. The total quantity of raw fuel used was 609,186 net tons, of which 43 per cent was anthracite or semianthracite, 39 per cent semibituminous slack, bituminous slack and coke, and 19 per cent. subbituminous coal and oil gas residue.

Bentonite, the colloidal clay found so abundantly in Saskatchewan, has a much greater suspending power than ordinary clays. It is proposed by ceramic engineers, therefore, to use it as the medium for carrying the frit in enamelling, as it is desirable to reduce the clay content of the frit to a minimum.

## INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to other advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machine or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

- Summary Report of the Mines Branch, 1920.  
The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the development of the general mining industry of Canada:—
- Fuel Testing Laboratory.**—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.
- Ore-Dressing Laboratory.**—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.
- Chemical Laboratory.**—Analysing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.
- Ceramic Laboratory.**—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.
- Structural Materials Laboratory.**—Experimental work on sands, cements and limes is also undertaken.
- Applications for reports and particulars relative to having investigations made in the several laboratories** should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**
- Summary Report.** The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist report is required, or what subject they are interested in.
- Memoir 108. The Mackenzie River Basin, by Charles Camsell and Wyatt Malcolm.

# Ontario's

# Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

HON H. MILLS, Minister of Mines

## Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

## Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor-spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, portland cement, brick and tile, meet every demand.

## Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth \$48,128,387, of which the metallic production was \$27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

| Year.          | Value.      | Year.          | Value.       |
|----------------|-------------|----------------|--------------|
| 1891 . . . . . | \$4,705,672 | 1906 . . . . . | \$22,388,383 |
| 1896 . . . . . | 5,235,003   | 1911 . . . . . | 41,976,797   |
| 1901 . . . . . | 11,831,086  | 1916 . . . . . | 65,303,822   |

## Dividends.

Dividends and bonuses paid to the end of 1921 amounted to \$23,140,734 for gold mining companies, and \$84,388,185 for silver mining companies or a total of \$107,528,919.

## Mining Regulations.

A miner's license costs \$5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of \$2.50 or \$3.00 per acre, depending on location in unsurveyed or surveyed territory.

## Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

## Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

### THE ANNUAL MEETING

"Service through coöperation" was the keynote of the annual meeting of the Canadian Institute of Mining and Metallurgy in Montreal last week. This note was struck by the retiring president, Mr. W. R. Wilson, in his opening address, and it was reflected in no uncertain way in the resolution on fuel supply addressed to the federal government in which the meeting culminated.

The symposium on fuel supply with which the meeting was mainly concerned had been well conceived and presented the various phases in something like their proper proportions. The papers were excellent and were supplemented where required by well-informed discussion. The members studied the problem from the various angles in which it was presented by successive speakers, and were quick to seize and hold the salient points. When Dr. C. V. Corless epitomised the situation as "Alberta's coal — Ontario's market — the idle railways in between," the Institute's stand was made. The lengthy and dignified resolution forwarded to the federal administration at the end of the meeting merely expanded this idea.

This is the first occasion for many years past on which the Institute has taken concerted and determined action on a problem of national scope and importance. The problem is not, be it noted, merely a technical problem; it is one that involves mining, transportation, merchandising and research, and that affects seriously and directly every citizen of Canada. The Institute has tackled a national problem, with some prospect of a successful issue.

The interest and enthusiasm shown by those that attended the meeting is direct and indubitable evidence that activity of this sort is what is needed to make the Institute a vital force not only in the lives of its individual members, but in the community in general. Let us tackle big, national, worth-while problems in a generous spirit, and we shall have the energy not only to find the solutions for these problems and put them into effect, but likewise a never-failing surplus of energy to devote to our own affairs, peculiar to the mining industry and affecting principally ourselves. Let us, one and all, devote a fair share of our energies first, to the service of our country, and second, to the service of our fellow-members in the Institute, and the resulting benefit to ourselves will, in this case as always, more than repay us for our efforts.

The Institute has devoted its annual meeting for

1923 to a national problem well worthy of its best efforts. The result is most encouraging to those that have the welfare of the Institute at heart. We hope that this will provide a precedent by which the present and future executives of the Institute will shape their course.

### QUEBEC'S MINERALS

In commenting on the Quebec Bureau of Mines' report of mineral production for 1922, the Montreal "Gazette" remarks: "Quebec is not possessed of such large or varied mineral deposits as some of the other provinces." Unless this statement is meant to describe the **developed** mineral resources, it is at the least a bow drawn at a venture, and possibly is a libel on the province of Quebec. The statement is made so frequently in the public pass that it should not stand without correction.

The fact is that there has been so little work of exploration and prospecting done in the province of Quebec that the extent of its mineral resources cannot be properly gauged. Until this prospecting shall have been done, our best guide in judging the potential mineral production is the geological evidence available. This evidence points to the conclusion that Quebec will have eventually a production of minerals at least equal to any other province in the Dominion, excluding, of course, coal.

A number of causes have contributed to the slow development of Quebec's mineral resources as compared with, say, Ontario. Until comparatively recent years the mining laws made it so difficult for *bona fide* prospectors to secure the fruits of their labours that few of them cared to pursue their vocation in the province. The finds of mineral actually made were more by chance than as a result of deliberate search. Now, happily, the Quebec mining law is as good as any in the land and is administered in such a way as to ensure each and every prospector of honest and equitable treatment. The result is evident already in the numbers of prospectors that have invested time and money in the new gold district of northwestern Quebec.

It is certain that, now the prospectors have tested the mining laws and their administration in Quebec and found them so favourable to themselves, there will be a great deal of exploratory work done throughout the newer parts of the province from now on. Experience has shown that a mining boom, and particularly a gold mining boom, if conducted rationally and with even a modest degree of success, stimulates ac-

only among prospectors that lasts for years. Ontario had the early advantage of the accidental discovery of the Sudbury nickel deposits. The gold boom in northwestern Ontario was conducted with so little regard to the principles either of engineering or finance that it has virtually closed that promising district to development from that day to this. The discovery of Cobalt, accidental again, bred a new generation of prospectors, whose search has revealed the gold deposits further north, and now promises to disclose another productive area across the border in Quebec.

A third disadvantage under which the prospective mineral industry of Quebec has laboured is the disposition of the railways in the province, as well as of the larger areas of arable land. A navigable sea route to Montreal is decidedly an advantage to Canada and Quebec, but it has meant that the lines of railway are confined principally to a small corner of the province, and that corner not particularly favourable to mineral production. As the principal farming districts are in the same small sector along the St. Lawrence, the farmers have not aided materially in drawing the railways outward. Thus access to the possible mineral-bearing lands is difficult, and even were valuable deposits found by men searching from the canoe routes their inaccessibility would in most cases make them valueless.

For generations to come, Canada's chief market for her mineral products must remain in the United States and overseas. In the case of most minerals our annual production is already far in excess of our annual need, and there will be a growing disparity between our population and our output of minerals. In this export trade Quebec, with fifteen hundred miles of seaboard bounding a vast unprospected territory that promises much in mineral production, is bound to hold a commanding position. Her ports will serve directly the market surrounding the Atlantic—the largest market for mineral products in the world.

### THE PROPOSED COKING PLANTS

One of the three important points connected with our fuel problem that the Dominion Fuel Board has recommended to be fully investigated is the provision at strategic points of coke in large quantities for domestic fuel. These points are the large cities, the principal markets for domestic fuel. They can use all the motor fuel the coke-ovens can produce, and their manufacturing industries will consume various other by-products. Intensive farming, requiring artificial fertilizers such as ammonium sulphate, is practised most near the large centres of population, so this important by-product will find a ready market near by.

Of all the various useful materials resulting from the coking, the disposal of the vast quantities of gas

appears to present the only problem, and even this apparent difficulty disappears on closer examination. There is already a large market for gas in the cities, both for domestic supply and for industrial purposes, and a slightly cheaper supply would stimulate its use greatly. It has been stated on good authority that coke-ovens can be operated profitably in the way proposed even without the sale of gas, and the possibility of cheap gas can be based safely on this statement.

First consider the domestic use of gas. At present a good part of the cooking in cities is done over gas burners. This is capable of some extension. But the largest potential use in private houses is for heating. Gas is a more convenient fuel even than oil. At present it cannot be used for heating houses because of the excessive cost. If the price were brought down sufficiently many householders would use it for heating—a luxury, to be sure, in comparison with coal or coke, but a luxury of which many would avail themselves. After a few years the price of gas and its use would strike an automatic balance, probably at a point that would be highly remunerative to the vendors.

Certain manufacturing industries would be expanded and others established were cheap gas available, especially those that make use of reverberatory or crucible furnaces. Take, for instance, the manufacture of pottery. Within easy reach of Montreal there is available China clay, feldspar and quartz, the three requisite minerals, sufficient to support a thriving industry. The supply of labour is good, Montreal is already the chief point of entry and distribution for the pottery used in Canada, and there is a protective tariff. The only feature lacking at present (apart from human initiative) is cheap gas fuel. The proposed coking plants would provide that fuel.

Central coking plants may prove to be an important aid not only to our domestic fuel supply, but to our industrial progress. We shall follow with interest the investigation about to be undertaken on the recommendation of the Dominion Fuel Board.

### ARGONAUT

The long-expected re-organization of Argonaut Gold, Limited, has been postponed once more. The public is to be invited to buy another million dollars' worth of stock. As all the present authorised stock is already issued, the authorised capital is to be increased by that amount. It is time the facts of the case were stated publicly.

The Argonaut company is developing the property of the old Huronia company, north of Larder Lake, Ontario, under a coöperative agreement, the terms of which have not been divulged. It is not known publicly what relation the directors of Argonaut bear to the owners of the mine, that is whether the directorates are inter-locking. The mine promises to be a genuine

producer, though the presence of copper pyrite in the ore makes the extraction of gold difficult and expensive, and faulting and other irregularities in the ore-bodies have resulted in abnormally high mining costs. Though it seems probable that by careful management the mine can be made to pay for working, there is no evidence that it will be a big mine or that profits will be large. In fact, all the evidence available indicates that the mine management will have their hands full paying working expenses and interest on the comparatively small amount of capital invested in mine and mill, and that there is only a remote chance of there ever being a surplus for the payment of dividends on the relatively large issue of capital stock.

The obvious and usual course in such a case is to "squeeze out" the investors by means of a re-organization of the company, when the resulting new concern can operate profitably, provided the mine and mill give a favourable balance. Instead of this, the directors propose to raise money to re-imburse themselves for advances (of stock) made, to pay off the owners in the Huronia company (who are they?) and to provide working capital. This will simply add to the burden, already hopelessly heavy, that the little mine now carries, and will merely accentuate the crash when it comes — for it is bound to come.

The Argonaut directorate have been running a bluff for many months. Their intention may be right, but their action is most decidedly wrong. The mining industry of Canada is bound to suffer through their mis-directed efforts, and the agony should not be increased or prolonged. It is high time this bluff was called.

We wish to draw attention to the letter on another page from Mr. J. J. Harpell. This corrects a statement made by Mr. E. P. Mathewson at the annual banquet of the Canadian Institute of Mining and Metallurgy last week, and also will serve to correct the false impression that Mr. Mathewson's mis-statement has spread abroad.

It is heartening to have the official announcement of the Lignite Utilization Board of the Federal, Manitoba and Saskatchewan governments that the experiments with lignite at Bienfait, Saskatchewan, are likely to be concluded successfully in the near future. The members of this board have no reason for making an over-hopeful announcement; in fact we would judge that their conclusion would be well on the conservative side. There have been rumors lately that the expenditure of nearly a million dollars at Bienfait had been wasted; we shall be glad to see still further evidence that the expenditure has been justified.

The colliery workers of Springhill, Nova Scotia, have offered to contribute to an old age pension fund for miners, provided the operators and the provincial government each contribute an equal amount. This

would appear to be a fair offer, of a sort calculated to help on towards the much-needed stability in labour conditions.

### SYNTHETIC KEROSENE!

Many stories have been told and a multitude of articles have been written concerning the development of the process of crude oil refining. The following incident is vouched for by an anonymous chronicler, whose imagination apparently sometimes works overtime.

Of all refining systems in use, a town in Wyoming boasts the one which has the world beaten.

In the shallow fields of this area there is very high gravity crude oil and occasionally there is found a spring where crude oils runs out on top of the water. During the dry season one summer, a farm boy was herding the family cows near one of these springs so that he could catch frogs during his idle moments. One evening, after milking, the boy's mother noticed that the milk smelt like gasoline. She called her husband's attention to it and he immediately held a lighted match to the pail and found to his surprise that the contents would burn. He then secured a hydrometer, and upon weighing the milk found it was a mixture of kerosene and gasoline.

The boy was called and queried, and at once the family set out to ascertain why the milk had been spoiled. They found that the cows had been drinking this water with crude oil floating on it. That gave the old man an idea and he gradually increased the amount of crude oil in the water until he had his cows drinking the pure stuff.

Then, by a little experimenting he found that he could milk four times a day and get some four gallons of 58 gravity gasoline and one-half gallon of 42 gravity kerosene each time. So he increased his herd and began bucking the refineries with the result that it was not long until he was forcing prices down. Soon he was not only supplying his home town, but laying pipe lines to other nearby centres and supplying the latter with their gasoline and kerosene.

The chronicler concludes by stating that the last he knew of the man was that he had resigned his job and was spending his winters in California and his summers in Muskoka, fishing and trying to keep his money down so that he could count it. — Imperial Oil Review.

### APOSTROPHE — WARNING

Editor, high on Olympus,

Calmly complacent, serene,

Why do you constantly crimp us?

Answer me squarely, old bean!

Editor, sinless, impeccable,

Pretermite preaching a while;

Pray do not think for a second

That we are compounded of guile.

Editor, perched on a pinnacle,

Lofty, contemptuous, remote,

Gee! what a biff on the binnaele

You'll get when I capture your goat!

J. C. M.

## "Of Sundry Minerals And Metals"

By J. C. MURRAY

Towards the closing years of the reign of Queen Elizabeth, there was written and published in London a book of unique interest. The author was one William Harrison, a Church of England clergyman. His book is the "Description of Britain and England." It appeared in the year 1587. To quote the erudite editor of the modern edition of Harrison, "the book is a deliberately drawn picture of Elizabethan England."

We cannot here touch (alas!) upon the entrancing chapters in which Harrison discourses on the manners, morals, and customs of his fellow Elizabethans. These chapters are photographically minute in detail, jewelled with kindly and caustic human touches, and pre-eminently readable. Only two chapters are pertinent to our present purpose.

The first of these is entitled, "Of Sundry Minerals and Metals." The chapter opens with a tirade against Englishmen for their besotted ignorance of their country's natural wealth. "There is no temporal commodity", writes Harrison, "necessary to be had or craved by any nation at God's hand that he hath not in most abundant manner bestowed upon us Englishmen, if we could see to use it and be thankful for the same." So little appreciative, indeed, were Englishmen of nature's bounty to them, that foreigners, says Harrison, would boast of buying the "case [skin] of a fox" from an Englishman for a great (four pence), and selling him back the tail alone of the same animal for twelve pence! "Would to God we might once wax wiser and each one endeavour that the commonwealth of England may flourish again in her old rate and that our commodities may be fully wrought at home... and not carried out to be shorn and dressed abroad." A sound petition, as appropriate to Canada today as it was to the England of Elizabeth's time!

"But to my purpose." In England, we read, there was great plenty of quicksilver, antimony, sulphur, black lead, and red and yellow orpiment. In addition, natural "cinnabarum" was found in abundance, and "the sulphurous glebe called bitumen in old time... burned in lamps when oil is scant." "Geson," which we take to be plaster of Paris, is mentioned, as also are chrysocolla, copperas, and "mineral stone, whereof petroleum is made". In sundry places, distant from the shore, the mineral pearl was digged out. "They are for greatness and colour most excellent of all other". (What would Mr. Dana say to that?) The author here laments that a great abundance of "rare and excellent commodities" had in times past been washed away from both Cornwall and Devon by the violence of the sea.

Coal was little used in England in those days, chiefly on account of the execrable roads. Iron and steel smelting and forging was done with charcoal. Harrison deplores the rapid depletion of the fine old forests, and predicts the day when "sea coals" will be generally used.

"We have pits... of white plaster, and of fat and white and other coloured marble, wherewith in many places the inhabitants do compost their soil, and which doth benefit their land in ample manner for many years to come." Saltpeter, too, and "salt

soda", for powder-making and glass-making, respectively, were plentiful, and much fine moulding clay. A pious exhortation to thankfulness concludes this section.

The section on metals is introduced with the sweeping statement that "all metals receive their beginning of quicksilver and sulphur, which are as mother and father to them. And such is the purpose of nature in their generations that she tendeth always to the procreation of gold." Nature more often fails than not, we are told, because seldom are quicksilver and sulphur mixed in the right proportions to generate gold. This assumption is validated to Mr. Harrison's satisfaction by the fact that gold is so often found corrupted by other metals. On such tenuous threads hung much of the science of the age.

Passing reference is made to the gold brought to England by Sir Francis Drake on his return from the West Indies (1582), and to Frobisher's costly error in mistaking "dross", (pyrite probably), for gold, on an island encountered in his search for a shorter cut to the "peaceable sea and kingdom of Cathay... Such was the plenty of ore there seen that if it had holden perfect, might have furnished all the world with abundance of that metal". For this digression Harrison apologizes.

Tin was, of course, plentiful in Cornwall and Devonshire "and sundry other places"; lead in Devonshire and elsewhere. Pewterers, we are informed, who formerly made only pots and dishes for domestic use, had grown into such exquisite cunning that "they can in manner imitate by infusion any form or fashion." Considerable space is devoted to a discussion of pewter and pewter "garnishes", or sets. It is mentioned that on the Continent "a garnish of good flat English pewter... is esteemed almost as precious as the like number of vessels that are made of silver." The lead mines of Wales, we read, endured until the people had used up all their wood. Iron ore was abundant, particularly near Manchester. Though it was "fine and good stuff as any that cometh from beyond the sea," yet it was a little esteemed. Harrison deprecates his countrymen's indifference to the possibilities of the industry. A curious sentence occurs here, a metallurgical hope. The iron and steel produced in England needed toughening. The metal, thinks Harrison, was "easy to be made tougher, if our alchemists could once find the true birth or production of the red man, whose mixture would induce a metallic toughness unto it, whereby it should abide the hammer."

Of copper Harrison observes that it "is lately not found [discovered], but rather restored to light". The "governance" of English copper mines had been in the hands of foreigners, and "profit doth very hardly countervail the charges." The section closes with the statement that "brass" is found in England (in a natural state!), but in small quantities.

The second chapter with which we have to do is headed, "Of Quarries of Stone for Building."

In former times, Harrison points out, the use of building stone was confined to churches, monasteries, and palaces. In Elizabeth's time, however, noblemen and gentlemen had begun to look upon timber as "not

"much better than paper work, of little continuance." He confesses his inability to classify and describe the different stones used; nevertheless, he makes a brave attempt, prefacing his remarks with a strong protest against the manufacture and use of brick when such plenty of natural stone lay ready to hand.

Here is a touch that we can readily appreciate:—"Our elders have from time to time, following our natural vice in misliking of our own commodities at home, and desiring those of other countries abroad, most esteemed the Caen stone that is brought hither out of Normandy." He goes on to show that English quarries could supply stone of equal or greater merit. He lists "white free stone, slate, and mere stone... paving stone, toph [standstone]," and so on. "Whereby," he continues, "it appeareth that we have quarries enough in England...if the peevish contempt or our own commodities...did not catch such foolish hold on us."

Evidently experiments were then being carried on in moulding cement mixtures for building forms, for "we have now devised to cast it in moulds for windows and pillars of what form and fashion we list." And "Sir Ralph Burcher, knight, hath put the device in practice." Sir Ralph is quoted as affirming that the business would bring more profit in six months, employing six men, than the ordinary building trade would bring in six years employing twelve men. There is no evidence that Sir Ralph's sanguine expectations were realized.

The discovery of fossils in stones is reported by Harrison with frank amazement. He does not expect his readers to believe him.

But the burden of his song is ever the Englishman's crass indifference to, and neglect of, his country's resources.

\* \* \*

It is well-nigh three centuries since William Harrison was gathered to his fathers. His wit and wisdom are as vital today as when he perpetuated them on paper. The foibles and foolishnesses of mankind are the same in kind if not in degree. Harrison recognized and derided them for the benefit of all succeeding generations.

### JOHN ALEXANDER DRESSER

President of the Canadian Institute of Mining and Metallurgy

At the annual banquet of the Canadian Institute of Mining and Metallurgy, held in the Mount Royal Hotel, Montreal, on March 11th, Mr. W. R. Wilson introduced to the members of the Institute, as their President for the ensuing year, Mr. John A. Dresser.

Mr. Dresser was born at Richmond, Que., on June 27, 1886. After a preliminary education at St. Francis College, he took an Arts course at McGill University, obtaining his bachelor's degree in 1893 and his master's degree in 1897. Mr. Dresser followed this very thorough preparation by post-graduate work at Harvard. His first work after leaving the University was educational, and he was principal of Shawville Academy, Aylmer Academy, St. Francis College, and the Grammar School at St. Henri, successively.

During his studies at McGill Mr. Dresser became interested in geology and, this interest continuing and growing, in 1909 he joined the staff of the Geological Survey of Canada, but in a short time resigned to

become manager of the Lands Department of the Algonma Central Railway. While in this position he was instrumental in developing a considerable area of land, his geological knowledge being supplemented by good organizing ability. At the expiration of his contract with the Company Mr. Dresser took up consulting work in Montreal, and among many other investigations in recent years has been doing geological exploration for oil in the Peace River district on behalf of the British Columbia Government. He has been president of the Geological Section of the Royal Society of Canada and is a member of many learned Societies. He became a member of the Institute in 1902, and was Councillor in 1910-11, and again in 1916-17, as well as being Chairman of the Montreal Branch in the latter year.

Mr. Dresser's geological work has been varied, and his record of such work is voluminous. His reports on "The Copper-bearing Rocks of the Eastern Townships" and the Asbestos District of Quebec are part of the authoritative literature upon these subjects. He

MR. JOHN A. DRESSER

has studied the district around Lake St. John, Que., an area along the National Transcontinental Railway in Southern Quebec, and the Peace River country in British Columbia.

Mrs. Dresser, formerly Miss Jean Lindsay, is as charming in manner as her husband; in fact, those who have the privilege of knowing her have no difficulty in deciding that his "better half" inspires Mr. Dresser constantly to maintain his friendly and genial attitude toward his fellow men.

In appearance the President is a man of medium stature, heavily built, but very alert. Probably his eyes are his most striking feature; set wide apart, light blue in colour, they look one fairly in the face, giving the impression of uprightness and reliability, — an impression borne out by his record. His varied experience and well-balanced judgment, combined with his kindly disposition, are ample assurance that the Institute will have capable and faithful guidance during the ensuing year.

# The Annual Meeting

CANADIAN INSTITUTE OF MINING AND METALLURGY  
MONTREAL, MARCH 7th TO 9th

The Canadian Institute of Mining and Metallurgy's annual meeting in Montreal last week marked the culmination, though not the end, of a serious effort on the part of its members to investigate Canada's fuel problem and to point the way to a solution. That the problem might have a thorough examination from every angle, authoritative representatives of the bituminous and anthracite coal fields of the United States and the Welsh coal operators were invited to submit papers and to join in the discussion. The result was most illuminating and interesting, not only to the members of the Institute present, but to the public at large, as evidenced by the comprehensive reports of the proceedings published by the newspapers and studied by their editorial writers. The third day was devoted to topics of more purely technical interest, each important in its own field.

## The Business Session

The meeting was opened by the President, Mr. W. R. Wilson, president of the Crow's Nest Pass Coal Company, the principal coal producer in the Canadian west, who is one of the veterans of our mining industry.

After referring to a "cullud" version of the Red Sea episode, wherein the friction of Moses' rapidly waving wand congealed the surface and allowed the children of Israel to pass over in safety, Mr. Wilson opened the discussion of Institute affairs. The report of Council for 1922 was adopted and auditors appointed. A discussion on Institute publications was opened by the distribution of two parallel statements, showing in one a budget on the basis of the "Canadian Mining Journal's" offer to print free of charge the matter now contained in the "Bulletin", and in the other, the budget adopted by Council, providing for the present attenuated "Bulletin", edited by the secretary, whose activities will now keep him busy at headquarters. The discussion brought out the fact that the Institute's reserve funds had been drawn upon during 1922 to the extent of \$6,000, and that the bank balance had been reduced by \$3,500 during the year, giving an over-expenditure during the year of approximately \$9,500. The fact of the "Bulletin's" competition with the "Journal" in the field of technical journalism was well aired. At this meeting, as at previous gatherings, the consensus of opinion was that the "Bulletin" is a necessary agency in holding together the Institute's scattered members.

The amendment to the by-laws proposed by the Western members was unanimously opposed by the meeting, there being present no representative of those supporting the proposal. The by-law will be submitted by letter ballot to all the members.

## President's Address

In his presidential address, Mr. Wilson reviewed briefly the history of the Institute during the quarter century of its existence. The twenty-three charter members formulated a sound and lasting plan when they applied for incorporation in 1898. They gauged well the enormous potential mineral production of this half-continent, and provided in their plan for the development of a large and sound mineral industry.

Here Mr. Wilson interjected the remark that we had plenty of men to work our mines, as well as the deposits themselves, however dangerous the mining might be. Some people have the erroneous idea that miners can be frightened away from a dangerous mine; but his experience has been that white men are actually attracted by the danger. White miners like a risk.

During the twenty-five years of its existence the institute has increased in numbers on an average of 56 annually, and now has 1,620 members of all classes. Our mining industry has increased in like proportion, and it is evident that this annual growth will certainly not be retarded for many years to come, and may even be accelerated. This rapid expansion of the industry indicates the opportunity not only for young mining engineers, but also for investment.

The Institute is represented publicly by its President and Council. The successive Councils, under the guidance and stimulus of their presiding officer, have sought, successfully, to spread abroad the knowledge and sound principles they themselves possessed. This spirit of coöperation with his fellows is the white man's glory, and Canadian mining engineers have not failed to live up to their privilege. During the year 1922 the Institute has contributed 62 technical papers, of which 13 deal with geology, 5 with metallurgy, 14 with coal, 6 with metal mining, 8 with subjects related to Institute organization and procedure and 16 with sundry subjects. The common advantage of these papers and the discussion they provoke constitutes one of the most laudable objects of a technical institution.

In conclusion, Mr. Wilson upheld the principle of donations to the Institute funds, either by individuals or by companies. He pointed to the fact that the technical employees of mining companies derive tangible, and often very important, advantage from the Institute, which is reflected in their increased usefulness to their employer. It is only just, then, Mr. Wilson held, that this employer should refund to the Institute at least a small part of the gain resulting from its activities.

## Mineral Statistics

As usual, the first definite mineral statistics for 1922 were presented at this meeting. Mr. S. J. Cook of the Dominion Bureau of Statistics presented a 50-page report covering the Dominion. This showed an increase in the aggregate of 1.3 percent over the preliminary estimate published at New Years. The metallic products showed an increase over 1921 of 23.9 percent, being \$61,144,990. The most notable increase is gold, by 32.8 percent, the value being \$25,446,717. Non-metallies decreased in value 5.99 percent, to \$82,582,339. Structural materials and clay products increased 13.0 percent, to \$39,302,266. The grand total was \$183,029,595. Ontario, with \$65,370,366 to her credit, has increased her lead among the provinces. British Columbia stands a good second at \$39,166,614, while Nova Scotia and Alberta run a close race for third with \$28,804,474 and \$25,717,572 respectively. Quebec's \$16,799,688 is accounted for mainly by the asbestos mines.

This over-development of mines is due to an indiscriminate leasehold system and has resulted in an unprofitable industry, whose operation is seasonal, with high wages and high operating costs. There are 400 coal mines in this district — several times as many as are required. The coal is graduated in quality from anthracite at Banff and the best grades of bituminous at Fernie and coal in general of the most desirable qualities in the mountains, to lignite in the far distant plains of Saskatchewan. Provided freight rates are sufficiently reduced, the Alberta coal bin can be drawn upon for Ontario's use.

### The Idle Railways

At this juncture Mr. T. W. Gibson read a letter from Mr. M. J. Butler that had just been published in the Toronto "Globe." Mr. Butler, a veteran railroader, pointed out that the problem of delivering Alberta coal in Ontario has not yet been seriously investigated. He advises an attempt to haul trainloads of coal over the favourable grades of the Transcontinental Railway in large cars and with heavy engines specially designed for the purpose. He estimates that 5000-ton trainloads could be handled in this way and that the cost would be as follows:

| Destination             | Distance<br>miles | Freight per<br>ton |
|-------------------------|-------------------|--------------------|
| Winnipeg . . . . .      | 900               | \$1.95             |
| Cochrane . . . . .      | 1751              | 3.50               |
| Port Arthur . . . . .   | 1413              | 3.13               |
| Port Colborne . . . . . | ....              | 5.50               |

The water freight and handling from Port Arthur to Port Colborne should not exceed \$2.50 a ton, which, with a mine price of \$2.00 a ton, gives a total cost of \$7.50 per ton at Port Colborne. Should further investigation show that Mr. Butler's figures are borne out, the importance of Alberta's coal to Ontario is obvious.

Dr. C. V. Corless, managing director of the Mond Nickel Company, upheld Mr. Butler's stand and epitomised Canada's fuel problem in three phrases — Alberta's coal — Ontario's market — the idle railways in between. He pointed out that the stake we are playing for as a nation is at present \$100,000,000 a year, the amount we pay to our neighbor annually for coal. At the present rate of increase, we shall need 100,000,000 tons of coal annually in twenty years time. The huge dimensions of these figures warrant our best efforts to make use of our own coal, and the expenditure of the requisite few millions in well-directed experiments. We are up against a new problem; the transportation of coal by land for a distance of 1,500 to 2,000 miles has never yet been investigated.

### The Manitoba Market

"The Problem of Replacing Foreign Coals in the Manitoba Market" was discussed by Mr. G. B. Saunders, of the Consumers' Coal Company, Winnipeg. Mr. Saunders is leading the fight for Canadian coal in Manitoba, and during the present year the efforts of himself and his associates have been successful. He points out, however, that the fight is not yet won. There still remains some of the unwarranted prejudice against Canadian coal, and though Canadian coal now supplies 50 to 75 percent of the Manitoba market, there is danger ahead. Manitoba is a favourite dumping ground for coal from the United

States, which is brought westward cheaply in steamships and freight trains that would otherwise be empty. Mr. Saunders pointed out that much American coal was sent to Manitoba last fall that should have gone to Ontario. The larger coal dealers in Winnipeg are, in general, in close alliance with coal producers in the United States.

Mr. Saunders said that the coöperation of the Institute and its members would be a valuable asset to the Alberta mine operators if exerted on their behalf. All varieties of coal, in any quantity desired, are available in Alberta, and the public must be educated to its use.

### Alternative Fuels

Mr. W. R. Wilon, the Institute's president, here gave some illuminating facts concerning the coke made at his own by-product plant in Fernie. A series of experiments had shown that it is possible to make coke with 4 to 6 percent volatile that is much superior to anthracite, both in convenience and in calorific value. He urged the use of coke for domestic heating.

Mr. Pearce, of the Canadian Pacific Railway, reinforced this view, supplementing it with the idea of using non-coking coals in a similar way, by carbonizing them and then briquetting by means of the tarry material resulting from the distillation. If the fine coal were washed to remove ash-forming materials before carbonizing, its value would be much enhanced, since a reduction of, say, 10 percent in ash would raise the value of the coal by about 25 percent. Mr. Pearce concluded that Nova Scotia should supply Quebec with coal, and Ontario as far west as Hamilton. From there to Port Arthur there is a gap that might still have to depend upon coal from the United States.

Mr. Wanklyn, fuel controller for Quebec, remarked that if we are to be a full-fledged nation, we must have our own fuel supply. We can solve our problem if we tackle it. He urged the Institute to represent to the government at Ottawa that they must support the investigations recommended by the Fuel Board. "We are living on a volcano," he said. Coal at \$18 to \$20 is a luxury that Canadians cannot afford. To avoid this undue expense we must see that our populace is educated in the way of using the other fuels that cost less.

Mr. Guy Toombs, of Montreal, who is a specialist in freight traffic remarked that the fuel problem must be solved by ourselves, the private citizens of Canada, rather than by our government. He presented an estimate to show that Alberta coal can be landed at Georgian Bay ports at a freight cost of \$6.60 a ton. The present grain rate from Drumheller to Port Arthur is \$5.00 a ton, and coal could be handled somewhat more cheaply, say at \$5.00 a ton. Boat freight should not exceed 60 cents a ton, and handling at either end, 50 cents a ton. With a mine cost of \$2.00, the total at Georgian Bay ports would be \$8.60. This calculation is similar to that of Mr. Butler, except that it is based on existing rates, susceptible of some improvement if the traffic were of large dimensions.

Mr. Clayton D. Dean, of the Imperial Oil Company outlined in his paper on "Fuel Oil as an Aid to Civilization," the place of oil in heating. Oil is the highest form of fuel and is suited to certain special uses, for which it is invaluable. Its use for steam raising on board ship is now well established. For heating offices and public buildings it has been used with some success, but for private dwellings its use is limited.

### Coal from the United States

The liveliest discussion of the meeting centred round the paper of Mr. Geo. H. Cushing, representative in Washington of the Wholesale Coal Dealers' Association. Mr. Cushing pointed out the curious fact that Canada and the United States, with 70 percent of the world's coal supply between them, each has a Fuel Board at present for the purpose of investigating fuel supply. He argued that the present conjunction of circumstances that has led to a shortage of coal is accidental and will not recur. The coal mines of the United States are now perfectly equipped and well developed, and it is inadequate railway facilities only that prevent abundant supplies from coming to Canada. When these are improved, or when the cheaper water-routes are used to better advantage, Canada will be able to draw at will on her neighbor's huge supplies of both anthracite and bituminous coals, and for an indefinitely long time. As for an embargo on coal that is impossible, because the supply of Canadian newspapers might be cut off in retaliation, which would stop political propaganda in the newspapers — an impossible situation!

Mr. Cushing was perfectly frank about the desire of American coal producers to retain the profitable Canadian market of 22 million tons annually. If the water-borne coal of Wales undercuts them in price by 25 cents, they will cut 50 cents. If the Nova Scotian collieries lower their prices 50 cents, they will go them another 50 cents better. If Alberta coal is offered at \$1.00 lower, the American coal will be cut \$2.00, if necessary. Mr. Cushing decried too much emphasis upon international boundaries where trade is concerned, and pointed to Europe, where there is a free international trade in coal. He assured the meeting of a continuance of the same friendly attitude of his countrymen of the United States towards Canadians as has been to our common advantage in the past.

In replying to Mr. Cushing's arguments, Mr. W. R. Wilson pointed out emphatically that each and all of the points he had brought forward provided added incentive to Canadians to make themselves independent of outside sources of fuel supply. The people of the United States are good neighbors, certainly; but they are putting the interests of their own country first, and as soon as it becomes to their advantage to cut off the export of coal to Canada, they will not hesitate to do so. The American is the last man to excuse in a neighbor undue dependence. It behooves us to be up and doing, to make ourselves independent. Mr. Cushing acknowledged these remarks by saying that, if anything he had said had the effect of stimulating a spirit of independence among Canadians, he thanked God for it.

### Welsh Coal, and Anthracite

Mr. J. F. K. Brown, now chief engineer for the Hudson Coal Company of Scranton and formerly a member of the war-time fuel commission at Ottawa, was unfortunately not able to present in person his masterly survey of the "Relationship of the Anthracite Fields to Canada." His conclusion is, in brief, that anthracite is a luxury fuel, and its price is bound to rise year by year as the cost of mining it increases. This is a fact that cannot be overcome, despite our best endeavours. Gradually this enhanced price will force consumers, first in Canada and then in less remote regions to use cheaper and possibly less convenient

fuels. This change will be gradual, rather than the result of any radical move or any sudden charge.

The Monmouthshire and South Wales Coal Owners' Association sent a paper on "British Fuel for the Canadian Market." This contained a brief description of the Welsh coal fields and mining industry and intimated that plenty of coal is available for us there, if we wish to make use of it. It was stated also that if the Canadian market proved suitable, this Association might establish a permanent depot in this country.

Mr. Coombe, of the Engineering Institute of Canada, told the meeting of the arrangement made by their Montreal branch to take up the study of fuel where the Mining Institute left off; that is to investigate the uses of fuel with a view to improving furnaces and boilers and methods of firing and in general to make more rational use of the fuel available. He assured the Mining Institute of the hearty coöperation of the Engineering Institute in this investigation concerning fuel, and suggested that both might conduct campaigns of education on the basis of their findings.

### The Quebec Gold Field

Prospectors and fish were prominent in the excellent series of lantern slides with which Mr. J. W. Evans illustrated his paper on "A Preliminary Prospecting Trip in Northern Quebec." He pointed out that this is by no means a poor man's gold camp, as much expensive work is necessary to develop and prove a claim. The area over which gold is known to occur is almost, if not quite, as large as the adjoining area in Ontario, though very little work has been done on it so far. Two diamond drills are now at work in Rouyn township. Mr. Chadbourne, who was present at the meeting, mentioned that a small mining plant is being installed on the Powell claim in which he is interested.

The pending rush into the district in the spring provoked some discussion as to the best way of approach. Mr. Evans advocated the canoe route down the Kinojevis river from the Transcontinental railway near Amos. Mr. T. C. Denis pointed out that a summer road from Lake Temiskaming is already built as far as Micmac, and will be extended as far as Lake Opasatika, whence there is a good water-route into the gold area. Thus it would appear that the branch recording office it is proposed to establish will be placed at a convenient centre on Lake Temiskaming, unless it should be put in the gold area itself.

The question of forest fires, which are always a serious menace when the woods are full of men, some of them inexperienced and careless, was discussed and it was resolved that this question be brought to the attention of the proper authorities in Quebec. Mr. A. O. Dufresne, of the Bureau of Mines, Quebec, pointed out that all men entering the woods must now have certificates, which inculcate a sense of responsibility and serve as a check on carelessness. Mr. Denis said that it was intended to quadruple the present force of fire-rangers, if necessary, to prevent conflagrations.

Dr. H. C. Cooke, who mapped the new gold area last summer for the Geological Survey, described it briefly. There is an east and west band of Keewatin rocks four or five miles wide north of a band of sediments of the Temiskaming series, both cut by porphyry dykes. Already gold has been found at Lake Fortune on the western side of Boischatel township and on

Mr. Hiram Donkin's report for Nova Scotia showed a fairly satisfactory year during 1922, and indicated substantial progress during the present year. In addition to 5,558,574 tons of coal there was produced the following:

|                               |         |
|-------------------------------|---------|
| Gypsum, tons . . . . .        | 250,000 |
| Salt, tons . . . . .          | 4,250   |
| Motor fuel, gallons . . . . . | 246,600 |
| Gold, ounces . . . . .        | 870     |

Mr. Theo. C. Denis, and Mr. A. O. Dufresne of the Quebec Department of Mines were able to report a 15 percent increase in Quebec's output of minerals. There was no metallic production, as the copper mines had been closed down and there had been no market for Canadian chromite or molybdenite. The developments in the new gold region of northwestern Quebec provides hope for the future of gold mining in the province.

Mr. Thos. W. Gibson, Deputy Minister of Mines for Ontario, mentioned, as had Mr. Denis and Mr. Cook before him, the present coöperation of the Department of Mines throughout the country with the Dominion Bureau of Statistics in gathering information, to the benefit and convenience of all concerned.

Mr. W. R. Rogers, of the Department of Mines, Toronto, pointed to the fact that Ontario has at last overtaken California in gold production, being \$6,000,000 ahead in 1922, and last year produced as much gold as Australasia. Ontario and Quebec now have a common interest in the two gold belts on which are situated the Porcupine and Kirkland camps. Among the present prospects in Ontario, the Goldale, Newray and Rochester are notable. The 15-page report presented by Mr. Rogers contains a table giving the annual and total productions to date of the various silver camps in Ontario, since 1904, here published for the first time. The total is well over 330 million ounces.

No report was made from the other provinces.

#### Wood Fuel

The first paper of the symposium on fuel was read by Mr. Rolland D. Craig, of the Forestry Branch, Ottawa. Mr. Craig pointed out that in the more thickly settled parts of Ontario and Quebec, where the soil is almost all useful for cultivation, even the agricultural communities are now dependent on fuel brought from afar. A wood-lot, if perfectly managed, can produce as much as one-half cord of wood per acre annually; but few wood-lots are thus cared for. As a cord of wood is the equivalent of a ton of coal, and as it takes about 15 tons of coal a year to heat the average house and do the cooking, a wood-lot must be at least 30 acres in extent to serve a farm-house from its annual growth. Only farmers with rocky or sandy land can afford to keep so large an area under trees.

On the outskirts of settlement and in the rocky areas that will remain permanently wooded, there is an entirely different case. In the areas now being cut over for timber and pulp-wood, there is a large proportion of hardwood, most of which is wasted at present. This could be turned into charcoal readily if there were a market for it. Mill refuse, which constitutes over one-quarter of the saw-log, is now burned merely to get rid of it. The briquetting of sawdust and similar small refuse has been accomplished commercially, and many provide a first-rate fuel from this hitherto useless material.

In relation to the total need for fuel, the available supply of wood fuel is small, and the best it can do is

to supply communities in favourable localities and to supplement other supplies. In this connection Mr. Thos. W. Gibson told of the unprofitably cord-wood venture of the Ontario government during the coal famine of 1918, when it was found very difficult to get people accustomed to anthracite to use any other fuel.

#### Lignite

After 45 years of mining, the annual production of lignite from the extensive beds in Saskatchewan is 350,000 to 400,000 tons, 90 percent of it coming from the Souris valley. The paper by Mr. R. J. Lee, chief Inspector of Mines for Saskatchewan for the Federal administration, summarised the resources, their present use, and the experiments conducted with a view to extending their use. It is the cheapest coal in Canada, averaging \$2.40 per ton at the mines. Much of it is won in open cuts, by steam shovel. The experiments at Bienfait with a view to improving the quality by low temperature carbonization are still in progress, and there is hope that they will be ultimately successful.

Dr. D. B. Dowling, of the Geological Survey, who is well acquainted with the field, pointed out that owing to the 33 percent of water in lignite and its inability to stand shipment or storage, Alberta coal now holds the field in Saskatchewan and Manitoba. If the carbonising and briquetting plant becomes commercially feasible, the high-grade fuel might stand shipment well into Ontario.

#### A Keen Analysis

In opening on Thursday morning the session of which he was chairman, Dr. W. H. Collins, Director of the Geological survey, gave a very thoughtful résumé of Canada's fuel problem as he sees it. During the last 25 years the population has increased 80 percent, the railway mileage, 120 percent, and the manufacturing industry, 700 percent. It is this rapid change from unspecialized pioneer conditions to a highly organized industrial community that has brought in its wake the fuel problem. The mechanical energy required is in proportion to the degree of industrialization. In 1900 we required 8 1/3 million tons of coal; in 1921, 31 million tons, an increase of 275 percent. In 1900 we used 1 1/2 tons of coal per capita; in 1922, 3 1/2 tons.

This rapid increase in the use of coal involves a diminishing ratio between the visible supply and the demand. It may be that the present shortage indicates that, in view of this diminishing ratio, the producers are protecting their supplies and enhancing their profits. Whatever the reason, the situation for us is grave. There may be no shortage next year, but unless we modify the sources of our fuel supply, it is certain to recur periodically. The remedy will be brought about by operators in the various districts and large consumers when they are convinced that the demand for fuel is permanent and that it can be satisfied at a profit. An emphasis of the permanency of the need may hasten this solution, and the duty devolves upon the Institute of helping by an emphatic statement. The Lignite Utilization Board, the Advisory Research Council and the Dominion Fuel Board are likewise agencies whose duty it is to conduct well-founded campaigns of propaganda and education, along with the Institute, to aid in the solution of the fuel problem.

Dr. Collins concluded by pointing out that the In-

secretary had been fortunate in securing such well informed speakers to contribute to its symposium on Fuel.

### Dominion Fuel Board

A general discussion of Canada's fuel problem was commenced by the paper by Mr. B. F. Haanel, of the Mines Branch, Ottawa, and a member of the Dominion Fuel Board, on "The Fuel Situation in Canada." This paper reviewed the sources of heat energy available and their distribution, and the conclusion was that within the "acute fuel area" in Ontario and Quebec, no single expedient will solve the problem. It will be modified, however, by the transportation eastward to the economic limit of Alberta coal, by the use of peat, by the substitution of coke for anthracite and by the increasing use of hydro-electric energy for power purposes in place of coal, as well as by the more economical use of fuel, both in the home and in the power plant.

Dr. Charles Camsell, Deputy Minister of Mines at Ottawa and chairman of the Dominion Fuel Board, outlined the case as it appears at present to that board, and announced the program the board has formulated and for the application of which they have applied for funds to the federal government. The board proposes that competent authorities be engaged to investigate three major problems:

1.—To determine the economic maximum annual production of which the Nova Scotian coal fields are capable. Mr. F. W. Gray estimates that there is a maximum of 5 million tons annually available for the use of Quebec and Ontario. Though this is five times the present supply from that source, it is much below the total required in that district. Though Mr. Gray is the best authority on this matter, the board considers that an independent investigation should be made.

2.—To investigate the possibility of converting bituminous coal into coke for domestic use. Last fall Dr. Camsell visited St. Paul and Minneapolis, where the anthracite formerly in use universally has been replaced almost entirely by coke, which is made in by-product coke ovens turning out 225,000 tons per annum. Coal at the coke-ovens costs \$12.50 per ton, and the coke is sold at the same price, the gas and other by-products making this profitable. To introduce the use of coke rapidly among householders 15 or 20 young fuel engineers were engaged as demonstrators, and their work proved very effective.

3.—To demonstrate the eastern limit to which Alberta coal can be shipped profitably. It has been shown that Alberta coal can compete favourably with coal from the United States in Winnipeg, but the markets farther east remain to be investigated.

Dr. Camsell concluded by remarking that the prejudice in Ontario and Quebec against peat, the only fuel available locally, must be overcome. Each and all of us must aid the home producer to the best of our several abilities. The series of papers on fuel presented at these meetings is, he said, a great aid to the Dominion Fuel Board.

### Bituminous Prices are Robbery

Dr. E. S. Moore, professor of economic geology at the University of Toronto, next drew on his long experience in the coal fields of Pennsylvania to bring out some important points. Though some important new reserves of anthracite coal have been determined

lately below the 3,000-foot level, he judges that 25 to 30 years from now no more anthracite will be available for Canada, as all the output will be required then in the United States. The obvious conclusion from this is that we Canadians should proceed at once to develop an alternative supply of domestic fuel. Bituminous coal, from the United States or elsewhere, will remain the chief fuel. But this must be converted into a high-grade fuel by coking. Coke can be sold profitably at the cost per ton of the coal from which it is made, the value of other products, such as motor fuel, gas and ammonium sulphate, making up for the expense of coking.

The present price of anthracite in Ontario (\$16.50 per ton) is, Dr. Moore stated, a fair price; but the present price of bituminous coal, which is the same to domestic users, is robbery. He estimates the cost of American bituminous coal in Toronto thus:

|                     |                  |
|---------------------|------------------|
| Mine cost . . . . . | \$2.00 to \$6.00 |
| Freight . . . . .   | 3.00             |
| Duty . . . . .      | .53              |

---

Total cost . . . . . \$5.53 to \$9.53

The discrepancy between these cost prices and the present selling price of \$16.50 per ton needs no further comment.

### Peat Fuel

Mr. Haanel's comprehensive paper on "Peat resources of the Central Provinces and their Utilization for Fuel Purposes" was supplemented by a series of lantern slides explained by Mr. E. V. Moore, engineer of the Joint Peat Committee, which has conducted the experiments at Alfred, Ontario, during the last four years. The experiments have resulted in the development of mechanisms that will produce a high-grade fuel at a cost to allow of their competing favourably with other fuels. The good quality of the fuel was amply testified by a number of the members that have used it.

Supplementing the information in his paper, Mr. Haanel explained that the object of the Peat Committee has been to demonstrate the use of peat as an auxiliary domestic fuel. Its use for power purposes may develop eventually. At Wilhelmshaven in Germany there is a steam plant of 20,000 horsepower fired exclusively with air-dried machine peat of a quality inferior to that made at Alfred. This peat competes in price with Welsh coal, which is available at a low price at that port. There is an unusually large content of fixed nitrogen in most Canadian peat, and eventually it may be advisable to save this by carbonising the air-dried peat, the remainder to be briquetted into fuel of the highest grade. In any case, an effective process for making air-dried peat is the first step, and in this the work of the Peat Committee has put Canada today in the lead throughout the world.

### Alberta — the Coal Bin of Canada

Mr. W. J. Dick, manager of a group of collieries in Alberta for North American Collieries, Limited, was not present to give his paper, an Economic Study of Coal Mining in Alberta and Southeastern British Columbia; so a synopsis was read by the secretary. Alberta, the "coal bin of Canada", has a million million tons of coal. The mines opened at present can supply three times the quantity used in the present markets.

various claims in Rouyn township. A few sills cutting the Temiskaming series had been determined, but not many. More detailed work is to be conducted during the coming summer.

Dr. Ami drew attention to the fact that the great "Huronian" belts of rocks as determined by the early geologists had proved to be productive of minerals, according to their prediction. In this connection he pointed out that the Canadian catalogue of scientific literature, formerly published annually by the Royal Society, has been dropped, and that this volume, so useful at home as well as abroad, might well be revived. It is possible that the former government subsidy of \$2,500 might be renewed were the volume again printed in Canada.

### Rock Drills and Researches

"The Evolution of Rock Drilling" was described by Mr. H. A. Burbank in a paper illustrated by a series of lantern slides. The modern rock drill began its career on this continent about 50 years ago as a rather crude appliance, with much the same outward form as the present piston drill. A radical change was made by the inventions of Leyner twenty years ago, which have resulted in the present hammer drill in its various forms.

Messrs. Elsworthy and Carnochan, of the Mines Branch, Ottawa, described their recent research in a paper, "Investigation of the Economic Value of a Fossil Resin from British Columbia." This resin is different from amber in the fact that it contains less succinic acid, and its physical properties make it unsuited to the ordinary uses for amber. It makes a varnish that is excellent but for its dark colour. The resin occurs in a coal seam at Coalmont, B.C. It is readily separated from the coal after crushing to 20 mesh by floating it off in a brine solution. This research, though it has not as yet resulted in findings of economic importance, illustrates the opportunities that lie on every side in the study of non-metallies.

"Notes on the Welding of Iron and Steel with the Electric Arc" was illustrated by Mr. F. H. Williams by an unusually fine series of photographs and micro-photographs of welded joints, and demonstrated the prime importance of painstaking and minute investigation in an industrial process such as this. Mr. Williams showed that with proper care and proper materials the electrically welded joint can be made almost perfect. Slag-coated welding rods are preferable to bare rods. Good steel plate must be used if a good weld is to result, as imperfections are accentuated by the recrystallizing induced by the heat of welding, which penetrates to a depth of 1/16 inch. Acetylene welding induces recrystallization for a distance of 1 to 4 inches.

### Maps and Miners

The value of topographic maps is appreciated now much more than formerly by the mining fraternity, said Mr. A. C. T. Sheppard of the Topographical Surveys Branch of the Geological Survey in his paper "Topographical Mapping and its Relation to the Mining Industry." Mr. Sheppard pointed out that a topographic map of suitable scale and style should precede each stage of mining development. The prospector entering virgin territory should have the preliminary map on a scale of 8 miles to the inch, showing the water-routes, and the principal topographic features by means of sketch contours, and the main geological

features. Next comes the map on a scale of 4 miles to the inch, which should precede intensive prospecting and preliminary mining development. This has surveyed contours, and shows trails, portages, etc., and more detailed geology than the first map. It can be used to aid in the location of roads and in railway reconnaissance and is of general use to the mining geologist and miner. As mining development proceeds, a high-grade map is required, and this is provided by the map on a scale of one mile to the inch showing both the topography and the geology in great detail. Here the public responsibility for mapping generally ends, as this map serves all requirements except for engineering projects. For this latter purpose maps (or plans) on a scale of 200,400 or 1,000 feet to the inch are used, all data being determined accurately by measurement, in distinction to the estimates and interpolations allowed on the former maps. Occasionally these plans are made at public expense for special purposes.

In conclusion, Mr. Sheppard pointed out that maps should be kept abreast of, but not ahead of, the need for them. Each map should be judged and used in relation to the purpose for which it was made; for instance an areal map should not be used as a basis for railway reconnaissance or as a guide for detailed prospecting. Geological and topographic information are very closely inter-related. The demand for high-grade maps is increasing very rapidly as mineral development proceeds.

The discussion following this paper brought out the fact that the various surveys departments (of which, as Dr. Ami pointed out, there are, or were recently, no fewer than fifteen in Ottawa) are not making full use of the aeroplane as an adjunct to their work. War-time experience demonstrated the marvellous accuracy and rapidity of this means of map-making. A motion was passed resolving that this matter be brought to the attention of the proper authorities in Ottawa, with a view especially to providing maps for the use of prospectors in advance of the progress of topographic surveys on the ground. It was pointed out also that the average prospector or mining engineer is still not fully aware of the vast amount of useful information available to him in Ottawa, and it was urged that means be developed to make this storehouse of information more adequately known to the public.

### Ball Mills in Action

The technical sessions were concluded by moving pictures showing the action of ball mills, which have been made during the progress of research in Toronto University by Prof. H. E. T. Haultain and Mr. F. C. Dyer. The three reels are a continuation of the series shown last year, and they illustrate vividly the genuine utility of this method of investigation. Both balls and discs were used in these experiments, dry and in water, and the use of two sizes of mill showed that a small mill simulates closely the action of a larger one. The coöperation of the Ontario government and the Film-craft company has made possible the progress of this fundamental research.

The three evenings of the meetings were well used. During the first Mr. W. S. Rugh, of the Consolidated Mining and Smelting Company, showed moving pictures illustrating the mining and smelting of zinc-lead-silver ore from the famous Sullivan mine. Mr. E. S.

Wilson gave in moving pictures "The Story of Compressed Air." On Thursday a boxing bout entertained those attending the annual "smoker" and concert. The banquet on Friday evening was the final event.

### The Banquet

The guests of honour at the banquet were Hon. Jacob Nicol, provincial treasurer of Quebec, Hon. Harry Mills, minister of Mines for Ontario, Mr. E. P. Mathewson, president of the American Institute of Mining and Metallurgical Engineers, and Dr. Bradley Stoughton, of New York. In his valedictory speech, Mr. Wilson dwelt again upon the opportunities Canada offers to young mining engineers and upon the duty each engineer owes to the industry through common and vigorous action as members of the Institute. An appreciation of Mr. Wilson's notable services to the Institute, both during his presidency and formerly, was voiced by Col. J. J. Penhale and Prof. J. W. Bell. Mr. Wilson introduced as the new president, Mr. J. A. Dresser, who stated his conviction that the Institute could, and would, render signal aid to the country in the difficult times that are ahead of us.

Mr. Mills, in replying to the toast to the guests, pointed to the recent rapid growth of gold mining in Ontario as an earnest of the future greatness of the industry. He affirmed the determination of his government to do all in their power to prevent "wild-catting" and to aid prospectors in every way possible, and paid a tribute to the excellent work being done by the Ontario government geologists.

Mr. Nicol emphasised the aid that road-building in the outlying districts gives to mining development and mentioned the comprehensive plan adopted by his government. Quebec, he said, has now good mining laws, calculated to stimulate and aid mining development. As for experimental legislation, he and his confrères are willing to wait until others have proved or disproved their theories.

### The Resolution on Fuel

The culminating point of the meetings was the resolution addressed to the Federal government, and passed unanimously, as follows:

"Whereas the inadequate and unsatisfactory supply of fuel for central Canada cannot be viewed with other than national concern. The shortage this winter has been experienced before, and is bound to repeat itself as long as present conditions remain.

"Whereas the importance of wood, peat and electricity, while not to be ignored, is in effect, an auxiliary factor only, and cannot seriously be considered as a substitute for coal. Eastern and Western Canada have the necessary coal deposits to satisfy fully, every requirement of Central Canada. Our railways are demanding increased traffic; and moving Canadian coal to meet our own necessities will supply them with tonnage, and relieve Canada's dependence on a foreign supply.

"Whereas the proper solution of many of our national problems is dependent upon scientific and industrial research, and one of the most crucial problems facing Canada today is this steadily increasing necessity of providing our own fuel requirements from our own resources; and

Whereas this Institute has been informed that the Dominion Government has appointed a Fuel Board to study and report on this problem—

"Therefore, be it resolved, in this annual meeting assembled, of the Canadian Institute of Mining and Metallurgy, that we voice our complete accord with such action, and express the hope that the report of the Fuel Board will result in the appointment of a Commission of Engineers, empowered to investigate in a practical way the entire problem of transporting and marketing Canadian coal to such areas as are today dependent upon foreign supplies, in the belief that transportation is the most important factor in the problem."

This resolution has now been placed in the hands of the government at Ottawa. If it has the influence on these administrators that it is designed to exert, the serious efforts of those that contributed time and energy to the annual meeting of the Institute will have been well rewarded.

### LETTERS FROM READERS

#### Mr. Mathewson and the "Journal"

To the Editor,  
Canadian Mining Journal.

Sir:

In the account given in the Montreal "Gazette" of March 10th of the speeches made at the annual banquet of the Canadian Institute of Mining and Metallurgy the preceding evening, the following paragraph appears:

"The rest of the meeting was devoted to a toast to the guests, proposed by E. P. Mathewson, president of the American Institute of Mining and Metallurgy, and other felicitous speeches. Mr. Mathewson termed himself the first Canadian-born president of the American society. His main thought was devoted to the publication, fostered by the Canadian Institute, of which he said: 'They have tried to steal your birthright and substitute for it a mess of pottage.' This referred to an attempt at the convention to forego the monthly bulletins of the Institute, and replace them by weekly space in the Canadian Mining Journal."

Such a statement must have been made in a moment of irresponsibility, and must not be allowed to go uncorrected.

Mr. Mathewson is not the first Canadian-born president of the American Institute. Dr. James Douglas, born in Quebec in 1837 and educated at Queen's University, was twice president of the American Institute. None knows this better than Mr. Mathewson. Speaking in Colorado in September, 1918, of the great work Dr. Douglas did for mining and metallurgy, Mr. Mathewson is credited with the following reference:

"Dr. Douglas was particularly thoughtful of his Canadian fellow countrymen and especially those who were engaged in scientific and educational work. Altogether the sums given by him during his lifetime to Canadian institutions would be probably up in the millions; but he was so unobtrusive and so retiring in his disposition that he seldom allowed his name to be used in connection with those matters. Anywhere in Canada, if you mention the name of 'Douglas', you will find people who will say at once, 'That was a great Canadian, a man we all revered'."

What a difference between the speaker on that occasion and the man he was extolling! Dr. Douglas did a big work for the land of his birth, and it will take many more than five years to efface from the memories of Canadians the recollection of the place he occupied. But, we ask ourselves, what has Mr. Mathewson done

for his native land that his fellow countrymen should experience a thrill of pride when he proclaims himself the first Canadian-born president of the American society? We refrain from discussing this question — for Mr. Mathewson was born in Canada, after all.

Now, what about this institution, the "Canadian Mining Journal", which Mr. Mathewson went out of his way to slander? This is one of the institutions for which Dr. James Douglas is largely responsible.

In 1907 the "Canadian Mining Review" was about to be purchased by an American contemporary. The prospect of the Canadian mining industry being left without a publication controlled by Canadians aroused some interest. The matter was brought to the attention of the writer by Dr. W. G. Miller, Provincial Geologist of Ontario, who suggested that a syndicate of Canadians should be organized to take over the "Review". The first man the writer sought for advice on the proposal was the late Dr. Douglas, who endorsed the suggestion and gave his cheque for part of the purchase price. This investment still remains in the company that owns the "Canadian Mining Journal". With this start the syndicate was formed, the "Review" purchased, the name changed to the "Canadian Mining Journal", and the foundation laid for the educational work that has since spread to all the other basic and essential industries of Canada.

Now, what about this "Bulletin" for which Mr. Mathewson professes such a high regard and such fond hopes? In the writer's experience (and he has kept in fairly close touch with the mining industry since 1907), there is only one occasion on which he can associate Mr. Mathewson with the "Bulletin" of the Institute. That was in 1917, when a small group of mining men, of whom Mr. Mathewson was one, met in Toronto to consider ways and means of keeping the "Bulletin" in print. On that occasion Mr. Mathewson did not offer to contribute one dollar. It was the owners of the "Canadian Mining Journal" that undertook to carry the "Bulletin" until the end of the war, which undertaking cost them over five thousand dollars. Last year the effort to keep the "Bulletin" in print cost the Institute a deficit in its funds of between nine and ten thousand dollars, and this year the deficit will be in the neighborhood of seven thousand dollars.

The offer that Mr. Mathewson referred to in such contemptuous terms was free space in the weekly issues of the "Canadian Mining Journal" for the publication of the material now appearing in the monthly "Bulletin". This would save the Institute from the annual loss it is now sustaining and at the same time would leave the secretary, who is now spending most of his time in editing the "Bulletin", free to do work of greater importance to the mining industry. Was there anything wrong in such an offer? Mr. Mathewson has made no offer. He is content to sit back and sneer at the suggestions of others. It was, moreover, obvious that Mr. Mathewson was not very serious in his attention at these meetings. He and his "fidus Achates", Mr. J. C. Beidelman, were conspicuous for their irresponsible interruptions at the initial session the only technical session they attended. This was hardly a service to the institute, or a proper example to the numbers of students who attended.

The Canadian Institute of Mining and Metallurgy and the "Canadian Mining Journal" are Canada's only two national mining institutions. To the outsider they reflect the size, importance and prestige of the mining industry and to those within the industry they give the best service their means will permit. Neither is bigger nor better than those in the industry make it. They

date back, the Institute for 25 years and the "Journal" for 40 years, and both represent the accumulated efforts of a long line of illustrious Canadians. Each has had a hard struggle against the domination of its older and wealthier contemporaries in the United States; but both are emerging from the struggle strong and vigorous. The "Canadian Mining Journal" now rests upon the secure foundation of a well established publishing business. It is published weekly, is well edited, and is giving a service to the industry that is generally appreciated. It always welcomes constructive criticism, but resents gratuitous slander.

The American Institute of Mining and Metallurgical Engineers is well thought of in Canada. The relations between that Institute and the Canadian Institute and the "Canadian Mining Journal" have always been most friendly, and the writer would be sorry to do or say anything that would give the least offence to the members of the former organization. When he read Mr. Mathewson's slanderous comment, the writer credited it to an irresponsible condition. If that is so, Mr. Mathewson has not had the grace to publish or offer an explanation and his statement cannot be allowed to stand unanswered.

Gardenvale, Que.

J. J. Harpell.

## ENGLISH CAPITAL AND ONTARIO GOLD MINES

The following extract from a recent number of "The Mining Journal," London, throws an interesting light on the reason why English capital has not been invested more largely in the Ontario gold industry:

"Under these circumstances it is certainly remarkable that gold mining prospects in Canada have not attracted general attention in this country. Conditions, of course, are not what they were before the war, and New York is much nearer than London; but when due allowance is made for these conditions, we cannot help the conclusion that there is far less enterprise existing at the present time among those connected with mining than was the case at the beginning of the century. The chief reason is no doubt the disappearance of the numerous smaller interests and the domination of the position by a few big groups more or less inter-allied. Inevitably the policy of such big concerns is to refuse prospects out of which small syndicates in the past might have done well, and take up only those which are capable of early flotation at high capitalisations, so as to secure a large and rapid profit on the turnover. In the end a policy of this kind, while profitable perhaps to the individual group, must be very restrictive of English enterprises in gold mining. We gather that at length somewhat more attention is being paid to Canada by the big gold mine promoting interests here, but considering that Ontario is British territory not more than a week distant from London, the evidences of a realisation of the potentialities of the situation are most disappointing."

The domination of the industry by big interests is well illustrated on the Rand where one mining house is said to control 50 per cent. of the mines and another 25 per cent. "Early flotation at high capitalisation, so as to secure a large and rapid profit on the turnover" cannot be accomplished so easily in a country where the industry is in its early stages.

During 1922 the coal mines of Belgium produced 92 percent of their pre-war output.

## A NEW ZINC PROSPECT\*

By F. J. ALCOCK.

The following report comprises a brief description of a property near the town of Renfrew, Ontario, on which zinc ore was found during the past summer. One day was spent by the writer on the property in October in company with the owners.

The prospect is situated on Lot No. 2 of the 3rd concession of Aldmoston Township in the County of Renfrew, approximately in the centre of the lot. It lies at a distance of less than four miles from Renfrew and an automobile can be driven right to the property. The owners are Messrs. William Dean and Joseph Legree, both of Renfrew.

### Geology

The general geology of the region is covered in a report by R. W. Ellis, "On the Geology of a Portion of Eastern Ontario," forming Part J of the Annual Report, Vol. XIV of the Geological Survey of Canada. More recent work has been carried out by M. E. Wilson, of the Geological Survey, in the seasons of 1918 and 1919 and a report by him on the district will be prepared in the near future. The following notes on the regional geology are largely from information supplied by him.

The solid rocks of the region are all of pre-Cambrian age and consist of sediments and igneous rocks cut by granite-gneiss and its differentiates. The sediments belong to what is known as the Grenville series of early pre-cambrian age. The commonest type is limestone. In this area it is white on the freshly broken surface, commonly weathering brownish, and is quite coarsely crystalline. A very characteristic feature is the presence throughout it of numerous rosettes and rods of tremolite. Associated with the limestones are bands of quartzite and fine-grained sedimentary gneiss which represent metamorphosed elastic beds which were deposited with the limestones. Two small areas of these rocks are visible near the zinc prospect.

The igneous rocks associated with the limestone consist of hornblende schists which in the immediate vicinity of the prospect underlie the limestone. They were originally either basic lava flows interbanded with the limestones or eruptives which have been intruded into them. The original character of these basic igneous rocks has been changed completely by the intrusion of the granites of the region. They are now black rocks whose freshly broken surfaces show a glistening appearance due to the cleavage faces of the hornblende crystals.

All these rocks are intruded by granite-gneiss. This rock is pinkish in colour and in composition is a biotite-granite. Certain phases are coarser grained and have been differentiated as pegmatite. These rocks have come up from great depths below the surface of the earth, thrusting through the older sedimentary and volcanic rocks. The heat and pressure accompanying their intrusion have highly altered these older rocks.

### Ore Deposits

The zinc ore lies in the Grenville limestone. One main trench twenty feet long and about ten feet deep running in a direction N 60 deg. W has been opened up and in two other places a little exploration work has been done. In the main trench is a good showing of zinc ore. The ore is sphalerite of a brown colour and resinous lustre. The commonest variety consists

of small grains disseminated through the recrystallized limestone, but small stringers of pure sphalerite are also locally found. A chemical analysis by Mr. Conner of a piece of the purest sphalerite that could be obtained gave the following results:—

|                                   |                |
|-----------------------------------|----------------|
| Iron, . . . . .                   | 3.36 per cent  |
| Zinc, . . . . .                   | 62.48 per cent |
| Sulphur (by difference) . . . . . | 34.16 per cent |

100.00

The disseminated ore shows considerable variation. In places there is a distinct banded effect with a strike of N 30 deg. E and a steep dip to the northwest. In the middle part of the trench are zones in which the disseminated ore consists largely of grains of sphalerite with only minor amounts of calcite. An assay of a specimen of the better grade of ore of this variety gave 37.02 per cent. zinc. In other places in the trench the recrystallized limestone contains only sparsely scattered grains of zinc blende. Small amounts of galena are also present. It is more abundant at the northwest end of the trench. An interesting feature in connection with the galena is a bluish tarnish visible on the cleavage surfaces. Iron pyrite is present in small amounts and a little chalcocopyrite is also to be found. At the west end of the trench rosettes of tremolite are very abundant in the recrystallized limestone. Sphalerite, galena, hydro-mica, chalcocopyrite and pyrite are found disseminated throughout this tremolite-calcite rock. At the eastern end of the trench some narrow veins of pink calcite traverse the limestone and carry small quantities of zinc blende. The deposit shows no definite boundaries and is irregular in both composition and structure. A grab sample consisting of chips taken from both faces along the entire length of the trench contained 9.95 per cent. zinc.

About 1200 feet northeast of the main pit a small amount of development work has been done on another outcrop of ore. The mineralization is here similar to that in the main pit. The limestone has been recrystallized into calcite and tremolite through which is disseminated sphalerite. The tremolite occurs both as feathery rosettes and also in good crystals which are colourless, white or grayish. The amount of ore exposed in this open cut is less than that in the main pit.

A third trench has been opened up about 200 feet southwest of the main trench. This shows recrystallized limestone with sparsely disseminated sphalerite and also some small veins of sphalerite.

### Conclusion Regarding the Deposits

The deposit is a contact metamorphic deposit formed by the action of the granite during its intrusion into the limestone and accompanying rocks. The limestone was apparently recrystallized with the production of calcite and tremolite and later solutions from the granite carrying sulphides impregnated the limestone. Almost identical deposits of zinc ore have been mined in the vicinity of Notre Dame des Anges, Portneuf county, Quebec. A detailed description of the various properties which have been developed in that area is given in the "Report on Mining Operations in the Province of Quebec during the year 1915." The quality of the ore in the Renfrew prospect as shown in the main pit is undoubtedly good. The property is very conveniently situated for mining operations. A railway siding is within 1 1-2 miles of the property and the power line from Calabogie to Renfrew crosses immediately over it.

\* A report submitted by Dr. Alcock to the Director of the Geological Survey, Ottawa, and published with his permission.

#### FOURTH REPORT OF JOINT PEAT COMMITTEE

The Department of Mines, Ontario, has now issued as Part IV, 1922, the "Fourth Report of the Joint Peat Committee," by B. F. Haanel, Secretary. Copies of this report were issued to the press as soon as it was passed by the Committee in December last, and there was a considerable amount of public discussion on it. It shows that an economical method of manufacturing peat has been developed, and recommends that the Committee be empowered to demonstrate its feasibility during the season of 1923. This recommendation was not adopted, however, and the future of the plant at Alfred, Ontario, and the process there developed is still uncertain. The report of 28 pages is well illustrated with photographs and a diagram.

#### ONTARIO MINES REPORT

Part I, Vol. 30 (1921) of the Ontario Department of Mines is now available for distribution. It contains the Statistical Review and the Mining Accidents for 1920, as well as the annual account of Mines in Ontario, Instruction Classes for Prospectors, the Third Report of the Joint Peat Committee, and Notes on Clay of the Missinaibi River, by Joseph Keele. The description of the mines of the province comprises 96 pages of condensed information as to mining operations and personnel, as well as numerous photos, plans and flow-sheets. The report on the prospectors' classes conducted in various centres where prospectors congregate during the winter mark the resumption of similar classes carried on fifteen to twenty years ago.

#### FORMIDABLE COAL RESERVES OF THE RUHR BASIN

In connection with the French seizure of the Ruhr district, the Temps (Paris) publishes an article explaining the resources and the conditions prevailing in that region. First of all, the Ruhr derives its prosperity mainly from its coal and lignite. Then, as a consequence of the gigantic coal exploitation, the entire district has become the center of hundreds of other industries, financial as well as manufacturing.

The coal extends over an area of 2900 square kilometers, and its visible reserves are estimated at 54,300,000,000 tons. At a level of 700 metres the amount is calculated at 11 billion tons, between 700 and 1000 metres 18,300,000,000 tons, and between 1000 and 1500 metres 25 billion tons. The probable reserves lying lower than 1500 metres are estimated by one authority at 75 billion tons and by another at 213 billion tons.

It would be possible to extract 100 million tons annually during 764 years to a depth of 1500 metres, or 674 years at a depth beyond 1500 metres, before exhausting the supply of good quality coal, and there would remain enough of inferior quality coal for 678 years. Accordingly, there is justification for Professor Frech's estimate that the Ruhr could yield 100 million tons of coal annually up to the year 4031.

As regards lignite, its reserves are estimated as being something more than four billion tons.

The exploitation of the Ruhr basin changed the entire economic life of Germany. The eastern coal regions of France, which had their great importance prior to 1871, had to drop to second place. It was on the coal of the Ruhr that the German "heavy industry" and the Prussian political power established their hegemony.

The city of Hamborn had 1396 inhabitants in 1871, but 110,803 inhabitants in 1920, thus showing an increase of 7937 per cent. Essen in the same period increased from 51,513 to 439,257. Dortmund had 41,813, and now about 314,000.

In the early days it was with foreign machinery (English and Belgian), with foreign labor and with foreign capital that the Ruhr coal industry was placed on a practical basis. In later years practically all these elements became German, and the pioneers were succeeded by such chiefs as Haniel, Krupp, Kirdorff and, still later, Thyssen and Stinnes. —The Protectionist.

#### INDUSTRIAL ITEMS

A manufactured material composed essentially of Canadian asbestos that has lately been introduced on the Canadian market is "Ferodo" bonded asbestos friction lining. This is composed of asbestos yarn spun round fine brass wire and then woven into a stiff fabric. Where more than one ply of this fabric is required, each layer is woven securely onto the one next on either side, so that the resulting mass is very securely put together. The fabric is then compressed in hydraulic presses into a solid mass that is eminently suited not only for brake linings but for stair trends, etc. It makes the highest possible grade of brake lining, especially suited for use on vehicles and mine hoists, where human life often depends directly upon its efficiency. "Ferodo" is made in England and the Canadian agents are the J. C. McLaren Belting Co., Montreal.

The Canadian Mead-Morrison Company, Limited, manufacturers of hoisting and conveying machinery and labour-saving plants, whose head office is in the Canada Cement Bldg., Montreal, and whose works are located at Welland, Ont., have recently announced their appointment as distributors of the Cello Projector, a practical motion picture machine that has been made for some time at their American factory. This machine is specially adaptable for use in scientific demonstrations, accident prevention, health propaganda, lecture rooms, and so on, and may be found of use in the mining industry with these objects in view.

Fraser and Chalmers, of Canada, Limited, Montreal, have recently installed for J. R. Booth, Limited, Ottawa a turbo-alternator of 2500 K. W. capacity, to insure ample power for the plant during the season of low water. Some such installation might prove a decided economy in the northern mining camps, where power shortages have become chronic.

The Combustion Engineering Corporation, Limited, has been incorporated under a Dominion charter to manufacture and sell in Canada a number of well-known lines of fuel machinery. The new company intends also to establish a research laboratory with a view to solving problems peculiar to Canada. The members of the firm are Messrs. A. J. T. Taylor, Wilfred R. Wood, J. Farmer, and G. C. Usher, who are well and favourably known in Canadian engineering circles.

During the year 1922 over two-thirds of the foreign trade of the United States was carried in foreign ships.

# The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

## NORTHERN ONTARIO

**HOLLINGER.**—At the annual meeting of the Hollinger held in Montreal recently, the President advised the shareholders that the Ontario Government had promised the company one of two power sites on the Abitibi River. The Hollinger is to get either the Island Portage power, 76 miles from the mine, which has a capacity of 40,000 h.p., or the Long Sault power, 56 miles from the mine, which is capable of developing 25,000 h.p. Either one of these two powers is ample to take care of the mine's needs. The official letter from the Government, however, on which this statement was based, does not sound quite as definite as the announcement, but indicates that some decision will shortly be arrived at. Mr. W. E. Raney, attorney general of Ontario, wrote that the Hollinger would be given a lease on either one of these powers on terms to be settled by Mr. Rowell, so that while there is every expectation that the matter will be shortly settled, it has not yet been completed. Some disappointment was felt that the dividend rate of the company was not increased, but the president stated that at the present time, on account of the power shortage, the company was not earning the regular dividend and that it was not considered advisable to increase the rate now on account of an estimated expenditure of three or four million dollars on proposed power installation.

**DOVE.**—During the month of February, the Dove mill treated 26,190 tons, or an average of 935 tons a day as compared with 1200 tons a day in January. It is understood, however, that the average grade in February was the highest in the history of the Dove Mines, so that the total revenue will be much the same as January.

**KIRKLAND.**—The Teck-Hughes workings have been connected with the Orr at the 400-foot level, and some good ore has been opened where the connection was made. The February production of the Teck-Hughes was \$106,200, from which a very substantial profit should be realized.

The Wright-Hargreaves has completed its main shaft to the 1000-foot level, and will now proceed with an extensive development programme. If results at the 700, 850 and 1000-foot levels correspond with those higher up, the capacity of the mill will be doubled.

**SOUTH LORRAIN.**—The Keeley is now the second largest silver producing mine in Canada, its monthly output being exceeded only by the Nipissing. The production for January was 115,000 ounces and in February 152,000 ounces, and developments underground indicate that this rate can be maintained for a considerable time. The company has recently declared a dividend of 8 per cent. and the shares are shortly to be listed on the Canadian market. Two veins in particular continue to show very good values, the "N" shoot of the Woods vein having been drifted on for a length of 200 feet and averaging 370 ounces across 19 inches. On the seventh level on vein No. 26 the drift has been driven for a total length of 74 feet and averages 2600 ounces across 15 inches. Vein No. 20, which is a branch from the Woods vein, has also been cut on the seventh level where it shows 12 inches of high-grade ore.

**IMPORTANT COURT DECISION.**—A decision of more than ordinary importance has recently been given by Mr. Justice Galt in Winnipeg, in connection with a suit brought by officials of the Brotherhood of Locomotive Engineers against a former secretary. The former secretary was discharged in May 1921 at the triennial convention in Cleveland, but refused to give up his position, claiming he had never been notified that his services had been dispensed with. The Brotherhood took an action to give an account of funds in his possession.

The case came to trial in December and was adjourned until January 15th. During the argument the counsel for the defence attacked the legality of the organization, claiming it was operating in restraint of trade, and asked that the plaintiffs be non-suited. The judge upheld the claim of the lawyer for the defence and non-suited the plaintiff. He stated that according to the law, the Brotherhood of Locomotive Engineers is an illegal organization operating in restraint of trade and as such cannot come to a court of law to adjust differences between itself and members of the organization. The judgment is said to be the only one of its kind ever delivered on the American continent, and is of far-reaching importance, as it affects all trades union organization. It is altogether probable, however, that it will be carried to the Privy Council.

## NOVA SCOTIA

**MINING THIN COAL SEAMS.**—When the Canadian National Railways lately refused to take any but screened coal from the Cumberland collieries, Springhill excepted, it created consternation among the owners of small mines in the Maccan, River Hibbert and Joggins districts. The Joggins Railway is fed by a number of these small collieries, the seams are usually thin, and the outputs small. They employ, however, a considerable number of men. But now that the slack coal has to be separated it is going to be increasingly difficult to continue to operate all these mines. The market for slack coal is very limited and the price per ton not encouraging. If no means can be devised to use the smaller sizes of coal, it will put these collieries back to the conditions prevailing twelve or fifteen years ago, when many of them were closed. At that time the quality of coal demanded by the market and the price paid were such as to prevent the development of all but the more favored seams of this district. Not until the war had brought larger prices and an indiscriminate use of all kinds and qualities of coal, did some of these little mines become real producers. Having reached this stage, it seems hard that their growth should be arrested by trade conditions, and means are being earnestly sought to use the slack that they may be kept going. The Nova Scotia government is interesting itself, and may be successful in helping to find the solution.

A number of years ago, owing to an inferior quality of coal produced, several of the small mines of this district were seriously affected and some were closed. An interesting experiment was tried by which the refuse material thrown out of the coal was saved and used under a specially built boiler to generate electricity.

A transmission-line was run from this plant to Amherst, a distance of fifteen miles, and the industries of that town operated by electric power. The plant is still in operation and is a success; but it took away part of the market for slack coal, while using up something less valuable. If low-grade material of this kind could be put to such good use, why should slack coal be debarred from our markets? With the present demand for coal we surely cannot be getting back to the days when huge slack piles were built up at different collieries only to be reduced to ashes by spontaneous combustion, if allowed to stay there long enough. This was a tremendous waste of good fuel and no repetition should be permitted.

It is the duty of the government to see that the fuel supply of the county is conserved, that coal is not lost underground by faulty methods of mining, or wasted overground when mined and brought to the surface. It may be that the methods of mining in these small collieries can be improved to reduce the quantity of slack coal made, and thus a better quality of coal sent out. If this were done the problem of mining profitably the thin seams would be easier of solution. It must not be forgotten that thin seams of coal cannot compete in the market on equal terms with thicker ones. While during abnormal times they may have had commercial value, yet in the nature of things most small seams will have to remain unworked until the larger ones are exhausted or until coal prices will permit of their extraction. This is especially true where there are low seams such as those of Cumberland county, lying quite close to larger ones of the best quality.

The Grand Lake District, New Brunswick, has a number of these thin seams, but no thick ones, so far as we know now. But these can all be worked because there are no large seams near by to compete against. Again, the seams lie quite close to the surface and the cost of putting down shafts is not much greater than the sinking of wells for water, in some places. Indeed, when ventilation, which is almost all natural, grown sluggish and the haulage roads get too long, it is found easier and cheaper to sink a new shaft than to continue to use the old road-ways and air-courses.

In Cape Breton the Dominion Coal Company is mining some of the thin seams, especially those that overlie the larger working seams. The Government insists on this to prevent the destruction of these seams by subsidence. But it is no hardship to work a thin with a thick seam, when both are owned and operated by the same company. The case for the thin seams of Cumberland County is not so easy, but in these days of unemployment and scarcity of fuel, nothing should be done to hamper the workmen and to affect adversely the consumer. Let us hope that a solution of the difficulty will soon be found.

### BRITISH COLUMBIA

**CANADA COPPER CONCENTRATE FOR TRAIL.**—The concentrate from the Allenby mill, near Princeton, will be shipped by the Granby Consolidated to the Trail smelter, Consolidated Mining & Smelting Co. of Canada, for treatment. This mill is a part of the plant of the Canada Copper Company which the Granby company is taking over. The suggestion that the output of the Allenby mill should be taken to the Anyox smelter is characterised by H. S. Munroe, General Manager, as impracticable. He states that the Granby company has not assumed control at Copper Mountain but that, as soon as it does the alterations necessary will be made to the equipment and the mill put in shape to handle its

capacity of 2,000 tons a day. Some 400 men would be employed at the new mine and mill.

**GRANBY PROSPECTS IN PORTLAND CANAL DISTRICT.**—In regard to the properties acquired in the Bear River section of Portland Canal, Mr. Munroe states that satisfactory progress is being made with the development of the Sunshine and the George groups. Some diamond drilling is to be done on the latter, which is about 20 miles inland. The Outsider group at Maple Bay is to be equipped with an aerial tramway and other requisite plant and a wharf during the summer. Between 30,000 and 40,000 tons of ore have been blocked out.

**GRANBY'S COPPER SHIPMENTS.**—The Granby company also announces a change in policy as to its shipments from Anyox of blister copper. Hitherto this has gone to Laurel Hill, Long Island. In future it will be sent direct to the Tacoma, Wash., smelter for refining. The Anyox smelter has been a heavy shipper through the port of Vancouver, an average of 1300 tons a month valued at \$450,000 going through that centre. Blister copper has been sent to Vancouver in coasting ships and transferred there to ocean craft bound for New York via the Panama Canal. This has involved payment of port, wharfage, and handling charges at Vancouver, together with insurance and freight to the Atlantic seaboard. Hereafter the ships Grifco, Amur, Anyox, Marmion and the fleet of barges operated by the Coastwise Steamship Co., a subsidiary of the Granby, will carry the concentrate direct to Tacoma.

**PORTLAND CANAL.**—George Clothier, government mining engineer stationed at Prince Rupert, whose district covers the Portland Canal section, is in Victoria on a fortnight's visit. He looks forward to a season of exceptional activity in the North. The Premier, B. C. Silver, Indian, and Big Missouri properties are looking well and numerous prospects are to be developed. Mr. Clothier speaks with enthusiasm of the outlook.

The Prince John group of claims, on the west side of Bear River four miles from Stewart, is reported to have been sold to the New York Exploration Company. In recent development work good milling ore was struck, the values being in copper and gold.

C. A. Banks, managing director of the B. C. Silver Mines, returned to the north a few weeks ago. It is stated that development work is proceeding so satisfactorily that it has been decided to increase the plant and to take on more men. Building materials and machinery have been ordered.

At the annual meeting of the Indian Mines Ltd. held at Prince Rupert, officers were elected as follows: President, Fred Ritchie and secretary treasurer, L. W. Patmore. Among the directors are G. D. B. Turner and George A. Turner. The capitalization has been increased to \$700,000 which, it is estimated, will permit securing plant and the defraying of other initial expenses incidental to bringing the property to the point of production.

**DUTY ON SCRAP PROPOSAL.**—A duty on scrap copper, scrap zinc and scrap brass, all of which now enter Canada free, is urged by the Associated Boards of Trade of Eastern B. C. in a resolution passed at a recent convention held at Trail. The position taken was that scrap metal is competing with the virgin metal produced in Canada and that it should be treated by the tariff on

the same basis as virgin foreign metal. A duty on all base metals entering Canada, up to the point where such metals can be supplied by Canadian producers, also is being recommended.

It is suggested that a delegation from British Columbia should visit Ottawa to advocate the establishment of an Ore Testing Plant in the eastern mining section of British Columbia.

**NEW COAL MINE.** The East Wellington Coal Mines Ltd. has been incorporated to develop coal lands west of the City of Nanaimo and adjacent to the abandoned workings of the "Jingle Pot" Mine. H. W. Maynard is president and J. J. Grant general manager. Good progress already has been made in the driving of the slope. The railway and wharves, together with much of the other plant of the old "Jingle Pot" are to be used. It is expected that production will be started within a month and that an output of 1,000 tons a day will have been reached in six months. It is the Wellington seam that will be exploited. Where it has been struck at a depth of 1100 feet it is five and a half feet thick. The property, it is estimated, will produce 11,000,000 tons.

**NEW COAL MINES REGULATION.**—As a result of recent fatal accidents in the Cassidy Mine of the Granby Consolidated Mining & Smelting Co. and the Wakesiah Mine, Western Fuel Corporation of Canada, regulations under the Coal Mines Regulation Act have been announced by the Hon. Wm. Sloan, Minister of Mines. They provide that "every percussive air drill used for the drilling of holes in coal shall be equipped with a water jet or spray, or other appliance equally efficient, to prevent the escape of coal dust, and of a type approved by the inspector of mines"; that "the use of a compressed air jet for forcibly removing accumulations of gas is strictly prohibited"; that "when accumulation of gas is being removed, the official in charge shall see that no person or persons or lights of any description are allowed on the return side of the gas being removed, unless at a sufficient distance away to allow of a proper diffusion of the gas to a percentage lower than the withdrawal point taking place before it reaches them"; that "the term 'properly fenced', as quoted in General Rule No. 6, shall mean a fence four feet high built of not less than three boards, 1" x 6", spaced so as not to obstruct the ventilation, and nailed securely to posts, or where there are no posts on the ribs, then the ends of the boards shall be hitched into the coal at least three inches and securely wedged"; that "all places fenced off as required under the terms of General Rules and Special Rules shall have securely attached to such a fence in a conspicuous place a danger signal properly worded, with the lettering at least four inches high; the lettering to be stencilled in white on dark background, both to be of durable material that will not easily become obliterated". In one of the accidents referred to the miner lost his life through disregarding a fence and entering a prohibited working. When he was found the boards were scattered and there was some doubt as to whether they had been in place when the workman subsequently overcame by gas, left his partner. In the other case loss of life resulted in the course of removing gas by means of compressed air. The regulations, therefore, are designed to meet effectively these two conditions.

**HIGH WAGES AND COSTLY COKE.**—The Dominion Government is to be asked to probe the whole question of coal mine operating costs and sales prices by the Associated Boards of Trade of Eastern British Columbia. At a Convention of that body, held recently at Trail,

Lorne A. Campbell, of the West Kootenay Power & Light Co., speaking on this subject stated that the wage scale at the mines of the Crow's Nest field was out of balance. The price of coke before the war was \$6.59 while now it was \$12 a ton. Success in the development of natural resources depended upon cheap coal. This was particularly true of low-grade ore bodies. In the Province of Alberta a reduction in the wage scale had been expected last April. The men had struck. While they were willing to accept a reduction, there had been an award in the United States that maintained the scale and the Alberta operators had been compelled to do likewise. The present scale would expire next April and Mr. Campbell suggested that something would have to be done in the meantime as "we must get cheaper coke".

**ALBERTA COAL FOR ONTARIO.**—At a recent meeting of the Edmonton branch of the Canadian Institute of Mining & Metallurgy the problem of supplying the Province of Ontario with coal was discussed and there was general disagreement with the reported statement of the Hon. Charles Stewart, Dominion Minister of Mines, on this subject. Mr. Stewart is reported to have said that with a charge of \$16 a ton for transportation against Alberta coal it was impractical to bring it to Ontario and that the only reasonable solution of the problem was to import United States bituminous coal and coke it in Canada. The Edmonton members said that the freight was \$12.50 a ton under present schedules. From a coal spur near the town of Edson, Alberta, to Prince Rupert, B. C., there was now a rate of \$3.40 a ton. If this mountain rate were applied on a ton-mile base to Toronto the rate would be approximately \$8 instead of \$12.50. That this should be done was the strong opinion of the meeting and representations are to be made accordingly to the Dominion Department of Mines. [Editor's Note — It is now learned that Mr. Stewart was misquoted, and that he stated \$16.00 to be the total cost of Alberta coal in Ontario.]

C. M. Campbell, resident manager of the Cassidy Collieries, Granby Consolidated Mining & Smelting Co., has returned after having spent a holiday in the South. During his absence N. E. Nelson, of the company's staff at Anyox, acted as manager.

### MINES BRANCH POSITIONS OPEN

Applications for two positions of interest to mining engineers will be received up to March 29th by the Civil Service Commission, Ottawa. These are, briefly, as follows:

**5044.**—Assistant chemist, Fuels and Fuel Testing Division, Mines Branch, at an initial salary of \$2,100. The duties are to share in the general activities of this plant, and the candidate is required to be a university graduate in science, or to have had equivalent experience.

**5046.**—Engineer, Ore Dressing and Metallurgical Division, Mines Branch, at an initial salary of \$1,680. The duties are to assist in milling and other tests in the metallurgical laboratories, and university graduation or an equivalent experience is required of the candidate.

The requisite forms of application can be had from the offices of the Employment Service of Canada, from the post-offices in the principal cities, or from the Civil Service Commission, Ottawa.

## A Guaranteed Pine Oil Supply

The best flotation frother is pine oil, refined and distilled pure oil. We are prepared to furnish you with a constant supply of steam-distilled pure oil of superior and uniform quality.

The Hercules Powder Co.'s three plants have two-thirds of all the plant capacity available for this product. Consequently, we can guarantee you a dependable supply.

Hercules Pine Oils are produced under strict chemical control and all shipments sent to you will comply absolutely with the original specifications.

We shall be glad to help you with your flotation problems.
